#### Abstract

We take advantage of the implementation of the Preferential Scholastic Subsidy (PSS) in Chile to test the effects of vouchers on academic achievement. The PSS has delivered extra resources to low-income, vulnerable students since 2008. Moreover, under this scheme, additional resources are contingent on the completion of specific scholastic goals. Using a difference-in-differences approach, we find a positive and significant effect of vouchers on standardized test scores. Additionally, our results highlight the importance of conditioning the delivery of resources to some specific academic goals when features of imperfect competition exist in the market.

Keywords: Vouchers; School choice; Academic achievement JEL Classification: H4; I2

## 1 Introduction

A central question in education economics is how to increase the quality of schools that lowincome students attend. Since Friedman wrote his 1955 essay on the role of goverment in education, many have considered the use of vouchers to be a promising way to increase the education quality supplied by schools (Friedman, 1955). However, at the empirical level, the literature is far from reaching a consensus. This paper contributes to the literature by providing additional empirical evidence on the effects of vouchers on academic achievement. Our results show that vouchers have a positive and significant effect on standardized test scores. Additionally, we show that focusing resources on specific scholastic commitments enhances the efficacy of vouchers in promoting a higher quality of education. Therefore, some conditionality in the delivery of resources seems to be an effective way of increasing students' academic achievement in markets in which some features of imperfect competition may exist.

At a theoretical level, vouchers can raise the academic results of low-income students through three main channels. First, simply, they allow low-income students to migrate from bad public schools to good private schools (if private schools indeed offer a higher quality of education than public schools). Second, vouchers introduce competition to public schools when they are inefficient local monopolies. When subsidies are allocated only to public schools, they face a fixed demand and thus have no incentives to supply a high education quality. Vouchers allow low-income students to migrate to private schools; the demand for public schools is no longer fixed. Therefore, if parents were allowed to choose freely among schools, vouchers should raise the education quality supplied by public schools in an environment where schools compete through quality supplied to the market. Third, if the incidence of the demand subsidy (the voucher) on the supply of education is nonzero, vouchers (or an increase in the resources delivered by vouchers to schools) increase the margin per enrolled students (the difference between the total monetary payments and the cost of educating a student) and thus encourage schools to attract more students. If there is competition, education quality increases within both public and private schools even if there is no migration of students from public to private schools (there would be greater competition within school types).

In 1981, Chile's government began to provide vouchers to any student wishing to attend a private school (called voucher private schools in this paper). The Chilean case provides a unique opportunity to analyze the transition from a centrally controlled public school system to one in which all families can choose freely between public and private schools. In order to test empirically the first channel mentioned above, we simply have to look at two pieces of data from the Chilean voucher experiment: first, the strength of the migration of students from public to private schools and, second, the difference in the academic performance in those types of schools.

Using data from the Chilean education market, Figure 1 shows a strong migration of students from public schools to private schools. Additionally, Figure 2 shows significant unconditional differences in the average results on a standardized test (SIMCE) ${ }^{1}$ between public and voucher private schools, although those results could be simply explained by differences in the socioeconomic background of students attending different public and private schools.

[^0]Up to 2000 , the literature had found that after properly controlling for students' socioeconomic backgrounds, public and voucher private schools saw a similar performance on achievement tests. For instance, Elacqua and Fabrega (2004) find that students attending voucher private schools do not necessarily outperform public school students and that competition has not necessarily improved the test results of both types of schools. Elacqua and Fabrega (2004) argue that the only thing that can be concluded from the Chilean experience is that free choice and competition have led to a further segmentation of the education system. However, these studies faced important limitations associated with the lack of control for selection bias, the estimation of homogeneous treatment effects across students with different characteristics, and the assumption that all publicly subsidized schools operate with the same budget (Sapelli and Vial, 2002). Subsequent studies show that after selection bias is controlled for, there is a significant difference in the academic performance of public and voucher private schools (Contreras, 2001; Tokman, 2001). Sapelli and Vial (2002) find that when they control for selection bias and student characteristics, there is a positive effect on standardized test scores in favor of voucher private schools. Some international evidence supports the results of (Sapelli and Vial, 2002). ${ }^{2}$

Therefore, the migration of students from public to private schools, where there is a difference in the education quality supplied by both types of schools, seems to be a valid channel through which the Chilean voucher system should have increased the academic achievement of low-income students. The evidence regarding the other two channels is more controversial.

Hoxby (2003) analyzes the impact that different programs had on school productivity: specifically, the effect of vouchers on achievement in Milwaukee public schools and the effect of charter schools on achievement in Michigan and Arizona public schools. Hoxby concludes that the regular public schools boosted their productivity when exposed to competition and that they responded to competitive threats that were surprisingly small. Neal (2002) concludes that while it is difficult to predict the outcome of any large-scale voucher experiment, voucher systems targeted toward large cities with a history of public school failure may have the greatest potential for yielding large benefits. Based on the work of Nechyba (1999) and Epple and Romano (2002), Neal conjectures that it is possible to design targeted voucher systems that would result in better outcomes for most if not all students in large urban school districts like those in Chicago and New York.

In other studies, the results are even less conclusive. Hsieh and Urquiola (2006) use the differential impact on enrollment that the introduction of a nationwide voucher has in Chilean communities to measure the effects of unrestricted choice on educational outcomes. Using panel data for about 150 municipalities, they find no evidence that choice improved average educational outcomes in Chile. Additionally, they find evidence that the Chilean voucher program led to increased sorting, as the best public school students left for the private sector.

Some empirical difficulties arise when we use the case of the Chilean voucher system introduced in 1981 to try to evaluate the effects of vouchers on the academic achievement of students (specifically, focusing on the second and third channels described at the beginning of

[^1]this section). Since 1981, more than $90 \%$ of schools have received vouchers. Therefore, the lack of a control group is one of the main empirical problems that scholars face in trying to evaluate the results of the Chilean voucher experiment.

We take advantage of the introduction of the Preferential Scholastic Subsidy (PSS) in Chile in 2008 to present additional empirical evidence on how vouchers affect academic achievement by (1) forcing public schools to compete with private schools and (2) increasing the profit margin per enrolled student in both public and private schools.

In 2008, the Chilean government introduced the PSS, which aims to improve the quality of education by giving an additional per-student subsidy to schools that voluntarily enroll vulnerable students. Under this scheme, additional resources are contingent on the completion of specific academic goals (the so-called Educational Improvement Plan [EIP]). In exchange for these additional resources, schools face two costs by joining the PSS scheme. First, they must accept vulnerable students, who are more costly to educate. Second, they are not allowed to charge a co-payment. This trade-off (more resources in exchange for educating more costly students and the prohibition of charging a co-payment) implies that only a fraction of schools decide to receive the PSS, thus generating a control group. Therefore, as discussed below, this new subsidy offers us a better opportunity to evaluate the empirical effects of vouchers on education quality.

Before the PSS was implemented, low-income, vulnerable students attended free public schools only. Public schools were forced by law to enroll students who wished to attend and were not allowed to charge any co-payment to them. Therefore, public schools faced a fixed demand by vulnerable students because those students did not have any alternative. Thus, public schools represented the kind of local monopolies argued by Hoxby (2003).

When the PSS was implemented, public schools received an extra amount of resources for each enrolled vulnerable student. In addition, a significant fraction of private schools became PSS receptors and began to enroll vulnerable students. The appearance of PSS private schools broke the local monopolies of public schools on vulnerable students. The demand by vulnerable students for public schools was no longer rigid and became responsive to changes in quality. Therefore, the PSS should have encouraged public schools to supply a higher education quality to avoid a massive migration of vulnerable students toward private schools ${ }^{3}$

Additionally, in public schools, the extra resources delivered by the PSS increase the margin per enrolled vulnerable student and thus encourage schools to attract more of those students by increasing the education quality supplied to the market. The same happens in private schools that become PSS receptors (those that charge a low co-payment, as we both theoretically and empirically show in this paper). Therefore, an increase in the academic achievement of students within public and private schools should be observed when the PSS is implemented, even if the migration of students from public to private schools would not exist.

Finally, some market imperfections (lack of information or geographic constraints) could prevent students from moving across schools. In that case, the demand is fixed (changes in quality are irrelevant) and the extra resources delivered by the PSS only represent economic rents for the owners of the schools. The PSS introduces a simple contract in which resources are contingent on the achievement of some minimum required quality under the. This conditionality

[^2]encourages the supply of a high education quality in markets where some features of imperfect competition exit.

Therefore, theoretically we expect the PSS to have positive effects on academic achievement. We test those effects empirically in this paper. However, some empirical difficulties arise. The migration of students from public to private schools could, by itself, affect the average academic achievement. For instance, assume that some vulnerable students with very low human capital migrate to private schools. If public/private schools are more/less effective in educating students with lower human capital, the average academic results could change even if nothing more happens. Additionally, the increase in education attainment for vulnerable students could also affect the average academic results of schools. To solve those difficulties, we control for students' socioeconomic backgrounds, which allows us to put aside the effect of changes in the composition of students attending public and private schools. Second, we include school-level fixed effects to control for potential self-selection of schools into the PSS program. Third, we use a difference in-differences (DD) approach. It allows us to remove the biases that result from the comparison of both groups in the second period and that can be explained by permanent differences between them and differences across time due to group-specific trends. ${ }^{4}$

We first use a sample of public and private schools. Controlling for students' socioeconomic backgrounds and for national trends, we find a positive and significant effect of the PSS on standardized test scores for math. For language, we find no significant effect under some specifications. These positive effects of the PSS on academic achievement (mainly in math test scores) are explained by a mix of higher competition for public schools and a higher margin per enrolled vulnerable student for both public and private schools. Moreover, after including school progress in the EIP, we find that a higher degree of accomplishment further raises test scores, in addition to the direct effect of the PSS. Those results show that focusing resources on specific scholastic commitments (i.e., the EIP in the Chilean system) enhances the efficacy of vouchers in promoting a higher quality of education in markets in which some features of imperfect competition may exist.

Next, we use a sample of only private schools. Even though two channels (more competition and a greater margin per enrolled student) operate for public schools and just one (a greater margin per enrolled student) operates for private schools, the magnitude of the effects is slightly greater for private schools. Our interpretation of these results is that public schools could face incentives different from the textbook case in which schools simply maximize profits. Sapelli (2003) indicates that a key element to evaluating the results of the Chilean voucher system is its design, which is far from the ideal case in which both public and voucher private schools operate under the same internal and external rules (i.e., under the same budgets and regulatory frameworks). In the Chilean case, public schools are regulated by a Teaching Statute and receive additional funds from municipalities when necessary. Together, these differences would determine the budget constraints of public and voucher private schools and, hence, the effect of competition on their academic achievement. Along the same line as Sapelli (2003), Hsieh and Urquiola (2006) show that despite extensive private entry and sustained declines in public enrollments, the aggregate number of municipal schools has barely fallen. Hsieh and Urquiola (2006) argue that municipal officials seem to have been unable or unwilling to close

[^3]public schools and, thus, public schools seem to not face strong incentives to compete. This is reinforced by the fact that, for these schools, revenue losses are mediated by municipal educational budgets, which makes it possible for them to lose students without automatic consequences on their resources. Thus, "soft budget constraints" for public schools could explain why the PSS has increased academic achievement in public schools but not by the magnitude suggested by our theoretical analysis. However, overall, our results confirm the positive effects of vouchers on academic achievement and the importance of conditioning the delivery of resources to some specific academic goals when features of imperfect competition exist in the market.

The rest of the paper is organized as follows. Section 2 reviews the institutional details of the PSS in Chile. Section 3 develops a theoretical model that analyzes the effects of vouchers on the quality of education supplied by schools in different competition environments. Section 4 discusses the empirical strategy used to test the main predictions of the theoretical model, and section 5 describes the data. Section 6 presents and discusses the results. Finally, section 7 concludes.

## 2 The Preferential Scholastic Subsidy (PSS)

### 2.1 The Educational System before the PSS

In 1980, Chile implemented several educational reforms seeking to improve education quality and the efficient use of resources by fostering competition between schools. Before these reforms, Chile had a centralized education system whereby the vast majority of schools were publicly financed and the Ministry of Education was directly responsible for designing and overseeing the implementation of all education policies, both substantive and administrative. ${ }^{5}$ Three main changes were particularly transformative. First, administrative responsibility over public schools was transferred from the Ministry of Education to each municipal government, resulting in a more decentralized configuration. Second, a new scholastic subsidy system was introduced as the principal financing mechanism. Subsidized private schools began to receive exactly the same per-student payment as the public (municipal) schools. To distinguish these institutions from the subsidized private schools that existed before the reforms (mainly religious), we will call them voucher private schools. The subsidy was calculated as a function of total student enrollment and average student attendance. Third, the government moved to actively encourage the participation of private entities in the financing and administration of educational institutions (Larranaga, 1995; Vial, 1998; González et al., 2002; Hsieh and Urquiola, 2003).

By making public funding directly contingent on student enrollment and retainment, schools should compete for a larger share of the student body by offering a better education. However, in their efforts to minimize educational costs and maximize funding, private and voucher private schools employed competitive admission processes to admit only the most promising applicants (Hsieh and Urquiola, 2003; Elacqua and Fabrega, 2004). In contrast, public schools with vacancies were legally obliged to admit all applicants regardless of their academic potential or socioeconomic backgrounds. As a result, those students who displayed more academic potential became increasingly enrolled in private or voucher private schools, while those

[^4]who displayed less academic promise were forced to enroll in municipal schools that, paradoxically, also received less funding. Because academic potential tends to be positively correlated with socioeconomic background, this segmentation resulted in the concentration of wealthier students in wealthier private or voucher private schools and more vulnerable students in poorer municipal schools.

In 1993, voucher private schools were allowed to charge students an additional tuition fee to complement the state subsidy (Larranaga, 1995; González et al., 2002). ${ }^{6}$ This system of shared financing encouraged schools with a better academic record to charge higher fees than their less successful counterparts, leading to increased socioeconomic segmentation and greater funding inequality.

Therefore, since 1993, the Chilean primary and secondary education system has been composed of three types of schools: (i) public schools financed by government subsidies based on students' attendance and by additional funds from local governments (municipalities); (ii) private schools that are also financed by the government and by co-payments made by parents (voucher private schools ); and (iii) private schools financed exclusively by parents (private schools). ${ }^{7}$

### 2.2 The PSS

Created in 2008, the PSS aims to improve the quality of education of the most vulnerable students by giving an additional per-student subsidy to schools that voluntarily enter the PSS program. By providing additional resources to less advantaged students, named priority students, the additional subsidy aims to both improve the quality of education received by priority students and decrease socioeconomic inequality in the academic performance of students from different socioeconomic backgrounds, through a combination of individually allocated additional funds and an incentive-based school reform program. Moreover, for the first time, under this scheme additional resources are contingent on the completion of specific scholastic reforms and improvements in school academic performance on a standardized test (SIMCE).

### 2.2.1 Who Are Priority Students?

The fundamental basis of the PSS is the targeted support of a specific group of underprivileged and vulnerable students through additional subsidies. To automatically qualify as priority, a student must meet one of the following criteria in order, proceeding to further criteria if and only if the preceding one is not applicable: (i) participation in the Chile Solidario program (a social welfare program protecting those in extreme poverty), (ii) being in the most vulnerable third of the population according to the latest measurement instrument, or (iii) belonging to the most vulnerable group in the National Health Fund (FONASA). If none of the preceding criteria are available, the student's position can also be temporarily established according to their family socioeconomic background.

[^5]
### 2.2.2 School Designations and Incentives under the Educational Improvement Plan

To receive PSS funds, schools are classified into three categories according to their academic performance on the SIMCE and the socioeconomic characteristics of their students. ${ }^{8}$ After a school is classified, it has to present an Educational Improvement Plan (EIP) to the Ministry of Education, which details educational reforms that the school will undertake to improve SIMCE results and how PSS funds will be spent to improve the academic performance of priority students. Although the amount of resources distributed to each priority student is the same for all schools and varies only by educational level, the autonomy of schools to decide how to use those resources and under what level of supervision will depend on the school's classification. ${ }^{9}$

While the EIPs form the central aspect of the incentives system inherent in the PSS law, in practice, they are only a part of the Equality of Opportunity and Educational Excellence Agreement (Convenio de Igualdad de Oportunidades y Excelencia Educativa) that each institution must sign. In addition to a commitment to produce and complete an EIP, the agreement also mandates that schools report the use of all resources received under the program and the status of specific projects, that all priority students must be allowed to attend free of tuition and costs (cannot be required to pay any co-payment), that all admissions must be open to any prospective student, ${ }^{10}$ and that schools must retain all students, even those with poor academic performance. These limitations on PSS funding and requirements for participation in the program are designed primarily to ensure that high-performing schools are accessible to all lowincome students and that schools are not allowed to give preference to highly qualified priority students.

### 2.2.3 Funds

PSS funding is allotted per priority student and delivered directly to the school instead of to any municipal funding system. It is calculated based on the average attendance rate of priority students over the previous three months, the school's classification as autonomous or emergent, the grade level of the priority student (younger students receive more resources), and the concentration of priority students in the school. Table 1 shows the monthly subsidy delivered per priority student in 2012.

In addition to the regular PSS funds, schools qualify for a subsidy if priority students make up more than $15 \%$ of the student body. Table 2 presents the concentration subsidy amount.

In relation to the current flat voucher based on student attendance, the PSS increases the resources given to schools for priority students by $70 \%$. Table 3 presents the amount of additional resources given by the PSS.

[^6]
## 3 The Model

In this section we build a model to analyze how the PSS affects the quality of education supplied by schools. We first assume an environment of perfect competition in which schools must offer a higher level of quality in order to attract more students. After doing so, we introduce frictions that break the assumption of perfect competition; for example, parents' lack of information and/or some geographical constraints may prevent students from moving across schools and thus produce a school-specific demand that is fixed. In this second model, we study the role that incentives attached to the delivery of PSS resources have on promoting a higher quality of education.

### 3.1 Perfect Competition

We assume that two types of schools exist: public and voucher private schools. Public schools are not allowed to charge any fee. On the contrary, voucher private schools charge a private co-payment that complements the resources delivered by a flat voucher. Voucher private schools are heterogeneous in the amount of the co-payment they charge to parents. Denote by $p_{i}$ the co-payment required by school $i$. We assume that $p_{i}$ has a continuous uniform distribution with a support $p_{i} \in(0, \bar{p}]$. Therefore, for public schools $p_{i}=0$, and for voucher private schools $p_{i}>0$.

We assume the following demand function of education:

$$
\begin{equation*}
n_{i}\left(q_{i}\right)=\beta q_{i} \tag{1}
\end{equation*}
$$

where $q_{i}$ denotes the quality supplied by school $i$. Therefore, the higher the quality supplied by a school, the greater the demand for that school. Assume that $q_{i} \geq 0$; that is, schools cannot supply a "negative quality."

On the demand side, there are two groups of students. The first group is composed of students from families who have zero income. Because their families have zero income, those students must attend free public schools. The second group is made up of students from highincome families. Those families have the resources to make co-payments and, therefore, can choose among any type of school. We assume the following cost function of providing a quality $q_{i}$ to high-income ( $h$ ) and low-income $(l)$ students:

$$
\begin{align*}
c_{h}(q) & =\underline{\alpha} q_{i}  \tag{2}\\
c_{l}(q) & =\bar{\alpha} q_{i} \tag{3}
\end{align*}
$$

$\forall \bar{\alpha} \geq \underline{\alpha}$. We assume a segregated education market in which low-income students attend free public schools and high-income students attend voucher private schools that require copayments. Figure 3 shows the average family income by school dependence. We can observe that segregation indeed exists in the Chilean education market.

Because low-income students do not have another alternative, the demand for public education by those students is fixed. Denote by $\bar{n}_{p}$ the fixed demand for public education. Public schools choose the quality level, $q_{p}$, that maximizes their profits:

$$
\begin{equation*}
\max _{q_{p}}\left\{\left(v-c_{l}\left(q_{p}\right)\right) \bar{n}_{p}\right\} \tag{4}
\end{equation*}
$$

where $v$ is the flat voucher received by both public and voucher private schools. It is clear that public schools have incentives to offer $q_{p}=0$.

Voucher private schools charge a co-payment and thus receive only students from highincome families. The maximization problem, which a voucher private school $i$ must solve, is the following:

$$
\begin{equation*}
\max _{q_{i}}\left\{\left(v+p_{i}-c_{h}\left(q_{i}\right)\right) n_{i}\left(q_{i}\right)\right\} . \tag{5}
\end{equation*}
$$

Therefore, the quality supplied by school type $i$ is:

$$
\begin{equation*}
q_{i}=\frac{v+p_{i}}{2 \underline{\alpha}} \tag{6}
\end{equation*}
$$

Notice that $\partial q_{i} / \partial p_{i}>0$. Moreover, it is straightforward to conclude that $q_{i}>q_{p}$ for all $i$. Therefore, voucher private schools offer a higher quality than public schools; and the higher the co-payment charged, the higher the quality supplied. Two main reasons explain why the quality of education in voucher private schools is higher than in public schools. First, positive co-payments in voucher private schools bring extra resources, so it becomes profitable to attract more students by increasing quality. Second, given that low-income students cannot afford a private education, public schools are local monopolies for that type of student. That is, the demand for those schools by low-income students is fixed. Therefore, total demand for public schools is nonresponsive to changes in quality, and, as a consequence, public schools do not have incentives to increase quality. The reason why voucher private schools with higher co-payments offer a higher quality is that higher co-payments increase the resources per student and thus encourage schools to attract more students by increasing quality.

Figure 2 shows that the average SIMCE score is higher in voucher private schools than in public schools. Additionally, Figure 4 plots the correlation between the co-payment level and the SIMCE score in voucher private schools. We observe a positive correlation, as predicted by the model. Therefore, the previous predictions of the model are indeed observed in the data.

### 3.1.1 The PSS System

We now assume that the PSS is implemented. As described in section 2, PSS schools have an additional amount of resources. Denote the total amount of resources (the flat voucher plus the extra resources) that a PSS school receives by $v_{P S S}$. Only schools that accept lowincome students receive the voucher $v_{P S S}$. Additionally, PSS private schools are not allowed to charge co-payments to vulnerable students. Therefore, the maximization problem for PSS private schools can be expressed as follows:

$$
\begin{equation*}
\max _{q_{P S S}}\left\{\left(v_{P S S}-c_{l}\left(q_{P S S}\right)\right) n_{P S S}\left(q_{P S S}\right)\right\} \tag{7}
\end{equation*}
$$

Therefore, the optimal choice of quality is:

$$
\begin{equation*}
q_{P S S}=\frac{v_{P S S}}{2 \bar{\alpha}} \tag{8}
\end{equation*}
$$

Schools that do not receive the PSS maximize the profits function (5); thus, they offer a quality level given by equation (6).

Voucher private schools that choose to receive the PSS are those ones for which benefits (the greater voucher) overcome costs (the loss of the co-payment and the higher cost of educating low-income students). Therefore, we can have a co-payment level $p^{*}$, such that schools that charge a co-payment $p^{*}$ are indifferent between becoming or not becoming PSS schools. Schools charging a co-payment lower than $p^{*}$ become PSS schools, whereas schools with a higher copayment do not choose to receive the PSS. The co-payment level $p^{*}$ is given by the following expression:

$$
\begin{equation*}
p^{*}=v_{P S S}(\underline{\alpha} / \bar{\alpha})^{\frac{1}{2}}-v \tag{9}
\end{equation*}
$$

We now impose the following constraint on $v_{P S S}$, such that a positive number of PSS and non-PSS schools exist:

$$
\begin{equation*}
0<p^{*}<\bar{p} \tag{A.1}
\end{equation*}
$$

Therefore, we have that

$$
\begin{equation*}
v\left(\frac{\bar{\alpha}}{\underline{\alpha}}\right)^{\frac{1}{2}}<v_{P S S}<(\bar{p}+v)\left(\frac{\bar{\alpha}}{\underline{\alpha}}\right)^{\frac{1}{2}} . \tag{10}
\end{equation*}
$$

As long as the value of $v_{P S S}$ satisfies inequality (10), some voucher private schools become PSS receptors and compete with public schools for low-income students. Additionally, all public schools have incentives to become PSS receptors and get the additional resources delivered by the PSS. Table 4 shows that this prediction is indeed observed in the data. Almost all public schools subscribed to the PSS, whereas around half of voucher private schools became PSS receptors.

Under the PSS system, the maximization problem of public schools is given by equation (7) and the education quality supplied to the market is given by equation (8).

### 3.1.2 Supply of Quality under a PSS and a non-PSS System

Now we analyze the supply of education quality of public schools in a PSS and a non-PSS system. Before and after the introduction of the PSS, public schools receive only low-income students. However, when the PSS is implemented, low-income students have the chance to attend those voucher private schools that become PSS receptors. Therefore, the demand for public schools by low-income students is no longer fixed but is responsive to changes in quality. Additionally, the PSS delivers extra resources to public schools, and, thus, the margin per enrolled student is higher under the PSS system. Both facts imply that public schools have incentives to supply a higher education quality under a PSS than under a non-PSS system. That conclusion is straightforward when we compare equation (8) with our previous conclusion that public schools supply a quality level $q_{p}=0$ when the PSS does not exist.

On the other hand, by comparing equations (6) and (8), we can establish that voucher private schools that charge a co-payment lower than some level $p^{* *}$ supply a higher education quality under a PSS than under a non-PSS system. $p^{* *}$ is the co-payment level that equals equations (6) and (8):

$$
\begin{equation*}
p^{* *}=v_{P S S}(\underline{\alpha} / \bar{\alpha})-v \tag{11}
\end{equation*}
$$

Figure 5 shows the relationships between $p^{* *}, p^{*}, q_{i}$ and $q_{P S S} .{ }^{11}$ From this figure, we can extract four main conclusions.

First, voucher private schools that choose to be PSS receptors are those that charge a co-payment lower than $p^{*}$. Voucher private schools must agree to receive private co-payments from parents. That cost is higher for schools that charge a higher co-payment. For this reason, the lower the co-payment, the greater the profitability of becoming a PSS receptor.

Second, voucher private schools that charge a low co-payment increase the education quality supplied under a PSS system more than under a non-PSS system. As discussed in the introduction, the receipt of more resources per enrolled student means it is profitable to attract more students, which encourages schools to supply a higher education quality. Under a PSS system, the margin per enrolled student increases more for schools that initially charged a low co-payment. That explains why those schools experience greater increases in their education quality.

Third, the unconditional effect of the PSS on the education quality supplied by voucher private schools is, in principle, ambiguous. As shown by Figure 5, there are some schools (those that charge a co-payment between $p^{* *}$ and $p^{*}$ ) that decrease their education quality compared with their counterfactual scenario (the non-PSS system). The optimal choice of education quality corresponds to the level at which the marginal cost of further increases in quality equals the marginal benefit. For schools with a middle-level co-payment (between $p^{* *}$ and $p^{*}$ ), the PSS system increases marginal benefits by a relatively small amount because copayments were relatively high under the non-PSS system. However, those schools could still have incentives to become PSS receptors. ${ }^{12}$.

Fourth, notice that as the difference between educating low-income and high-income students decreases, it is more likely to find a positive effect of the PSS on the average education quality supplied by voucher private schools. In terms of Figure 5, the difference between $p^{* *}$ and $p^{*}$ decreases when $\underline{\alpha} / \bar{\alpha}$ tends to one. For instance, if the difference in the cost of educating low-income and high-income students is null $(\underline{\alpha} / \bar{\alpha}=1)$, schools that choose to be PSS receptors are exactly those that would increase their education quality under a PSS system (with respect to the non-PSS scenario). A direct implication of the latter result is that, controlling for the socioeconomic background of students, we should expect an unambiguous positive effect of the PSS on the education quality of voucher private schools (keeping the composition of students constant is similar to imposing $\underline{\alpha}=\bar{\alpha}$ in terms of the model). In section 6 , we test all those empirical predictions of the model.

### 3.2 Imperfect Competition

In this subsection we deviate from the perfect competition environment. Indeed, we assume that both public and voucher private schools face a fixed demand $\bar{n}$. Some factors that may explain this school-specific rigid demand could be some lack of information for parents about school quality or students' mobility constraints. Both factors imply that an increase in the quality supplied may not attract more students. We can immediately conclude that the quality supplied by all school types will be the minimum- in this case, zero. Moreover, because the

[^7]quality supplied is zero, the PSS will be ineffective in promoting a higher quality of education. The extra resources would only be economic rents for the owners of PSS schools.

Schools will choose to receive the PSS if the following condition is satisfied:

$$
\begin{equation*}
p_{i}<v_{P S S}-v . \tag{12}
\end{equation*}
$$

Therefore, as long as $v_{P S S}>v$, there will be some schools that choose to receive the PSS. In these schools, the delivery of extra resources will not be effective in promoting a higher quality of education. They would only increase profits. A different type of contract must be designed to promote education quality.

### 3.2.1 The PSS Contract

The PSS contract in an environment of imperfect competition may condition resources to the accomplishment of some goals that ensure that PSS schools have incentives to offer higher quality levels of education.

Assume a very simple contract to emulate the EIP, described in section 2: in exchange for new resources, PSS schools must warrant a quality equal to or greater than $\bar{q}$. Assume that

$$
\begin{equation*}
\bar{q} \leq q_{p} . \tag{A.2}
\end{equation*}
$$

Assumption [A.2] implies that the constraints imposed by the PSS are not binding in an environment of perfect competition. Schools that subscribe to this type of contract face the following maximization problem:

$$
\begin{equation*}
\max _{q_{P S S}}\left\{\left(v_{P S S}-\bar{\alpha} q_{P S S}\right) \bar{n}\right\}, \tag{13}
\end{equation*}
$$

such that

$$
\begin{equation*}
q_{P S S} \geq \bar{q} \tag{14}
\end{equation*}
$$

Therefore, PSS schools choose to offer the minimum required quality $\bar{q}$, which is greater than zero.

As before, we can have a co-payment level $p^{*}$, such that schools charging a co-payment lower than $p^{*}$ choose to receive the PSS:

$$
\begin{equation*}
p^{*}=\left(v_{P S S}-v\right)-\overline{\alpha q} . \tag{15}
\end{equation*}
$$

As in the previous section, we impose assumption [A.1], which grants that a positive number of PSS and non-PSS schools exist. Assumption [A.1] imposes a limit to the value of $v_{P S S}$, as the following inequality shows ${ }^{13}$ :

$$
\begin{equation*}
v+\overline{\alpha q}<v_{P S S}<\bar{p}+v+\overline{\alpha q} . \tag{16}
\end{equation*}
$$

[^8]The quality supplied by schools when the PSS does not exist is simply zero. However, as long as the amount of the voucher satisfies the lower limit of inequality (16), there will be a positive number of PSS schools, and the average quality supplied by schools will be higher compared with that when the PSS does not exist. Therefore, when some frictions limit competition among schools, a contract conditioning resources to the accomplishment of some minimum quality level is effective in promoting a higher quality of education among schools.

## 4 Empirical Strategy

We use a difference in-differences (DD) approach to evaluate the effects of the PSS on academic achievement. According to this methodology, there are two groups observed in two time periods, where one is exposed to a treatment in the second period but not in the first (treatment group). The other group is not exposed to a treatment during either period (i.e., the control group). If the same units of the treatment and the control groups are both in the first and second periods, the effect of the treatment could be obtained by subtracting the average gain of the control group from the average gain of the treatment group. This approach allows us to remove the biases that result from the comparison of both groups in the second period and that can be explained by permanent differences between them and differences across time due to group-specific trends.

For two periods and a treatment that occurs only in the second period, we have the following expression:

$$
\begin{equation*}
y_{i t}=\beta_{0}+\beta_{1} d 2_{t}+\beta_{2} w_{i t}+u_{i t}, \quad \forall t \in 1,2 \tag{17}
\end{equation*}
$$

where $y_{i t}$ is the outcome and $d 2_{t}$ is a dummy variable that takes the value of 1 for the second period and zero otherwise. Also, $w_{i t}$ is a binary program indicator that is equal to 1 if unit $i$ receives the treatment in period $t$, and $u_{i t}$ is an error term. Taking differences, we have:

$$
\begin{equation*}
\Delta y_{i}=\beta_{1}+\beta_{2} \Delta w_{i}+\Delta u_{i} \tag{18}
\end{equation*}
$$

In this framework, $\beta_{2}$ is the treatment effect. Moreover, if the changes in the treatment status are not correlated with the error term (i.e., $E\left[\Delta w_{i} \Delta u_{i}\right]$ ), the OLS estimation of equation 18 will produce consistent parameters. In the case where there are no units treated in the first period, the OLS estimation can be obtained as:

$$
\begin{equation*}
\beta_{2}=\Delta \bar{y}_{\text {treated }}-\Delta \bar{y}_{\text {control }}, \tag{19}
\end{equation*}
$$

where $\bar{y}_{\text {treated }}$ and $\bar{y}_{\text {control }}$ are the sample averages of the outcome variable $(y)$ for the treatment and control groups, respectively.

We use a panel of schools in which we can identify those that signed the Equality of Opportunity and Educational Excellence Agreement and received PSS funds from 2009 to 2011 (i.e., the treatment group) and those that decided not to participate in this program during this period (i.e., the control group). In our model, the pre-treatment period is defined as the time before the PSS was implemented (i.e., from 2006 to 2008 ), and the post-treatment period as the time in which the PSS was in effect (i.e., from 2009 to 2011). We use the following baseline
specification to estimate the effects of the PSS on academic achievement, in a context of panel data:

$$
\begin{equation*}
\text { SIMCE }_{i t}=\beta_{1} \lambda_{t}+\beta_{2} w_{i t}+\beta_{3} X_{i t}+c_{i}+u_{i t}, \quad \forall t \in[1, T] ; \tag{20}
\end{equation*}
$$

where SIMCE $_{i t}$ corresponds to the average score that school $i$ obtained on the SIMCE (math and language, depending on the econometric specification) in the period $t, \lambda_{t}$ is a time trend, and $w_{i t}$ is a binary program indicator that equals one if the school $i$ participates in the program at time $t$ and zero otherwise. Additionally, we include a vector of school characteristics, $X_{i t}$, which contains the average gross family income and the education level of the parents of the students attending school $i$ at time $t$. Finally, we include a fixed individual effect $c_{i}$ and an idiosyncratic error term $u_{i t}$.

Equation (20) constitutes our baseline empirical model. It allows for aggregate time effects and controls. We estimate equation (20) using fixed effects to obtain the policy effect estimator associated with $w_{i t}$. We interpret it as the average effect of the PSS on schools' academic achievement.

The key identifying assumption is that the trend in test scores would be the same in both PSS and non-PSS schools in the absence of treatment. Although the treatment and control individual schools can differ, this difference is meant to be captured by the school fixed effects. Figure 6 shows the SIMCE scores in the treatment and control groups. We observe that the trends followed by those school groups are fairly similar until 2008. ${ }^{14}$ Treatment induces a deviation from this common trend. The treatment is composed by a higher margin per enrolled student and more competition (in case of public schools). Therefore, controlling by fixed effects and observable characteristics of schools, treatment and control schools are identical except by the fact that, after the PSS, the treatment schools face more competition (public schools) and receive a higher margin per enrolled student (public and voucher private schools).

## 5 Data

Our sample is composed of public and voucher private schools that were and were not exposed to the PSS from 2009 to 2011. This database contains information about students' socioeconomic backgrounds, including variables such as gross family income and the education level of the students' parents. Our database also includes information about the proportion of the EIP accomplished by schools that participated in the PSS in 2010. As we previously explained, the EIP is a plan that details educational reforms intended to improve SIMCE scores and establishes how financial resources provided by the PSS will be spent to improve the academic perform of priority students. Because schools define their EIPs over a period of four years, ${ }^{15}$ the Ministry of Education decided to carry out an evaluation before the end of the agreement. In 2010, the ministry evaluated the goals accomplished by schools in math, language, and management. We use the proportion of the EIP accomplished in math and language in 2010 as a measure of the educational reform progress.

[^9]We link this information with school academic performance. In particular, we include the average score that a school obtained on the SIMCE between 2006 and 2011. Considering that the PSS was progressively implemented in preschool and primary education (and only since 2012 in secondary education), we use schools' average scores obtained by fourth graders in math and language, which are the only measures of school performance available for the levels under the PSS.

Using this information, we build a panel for public and voucher private schools that allows a pre-PSS period and a post-PSS period. We define the pre-PSS period, or the pre-treatment period, as the three years before the implementation of the PSS. The post-PSS period, or the post-treatment period, corresponds to the three years in which schools could receive the PSS by signing an Equality of Opportunity and Educational Excellence Agreement (Convenio de Igualdad de Oportunidades y Excelencia Educativa). By signing the agreement, schools agreed to carry out specific measures oriented to improve the quality of the education provided and perform specific actions to encourage the school's retention and academic performance of priority students. Therefore, our panel links not only the participation status of schools in the PSS but also their academic performance on the SIMCE, the socioeconomic backgrounds of their students, and a measure of relative efficiency of the goals proposed in their EIP. Tables 5 and 6 show summary statistics of treated and untreated schools for each year.

## 6 Results

Table 7 presents the results of equation (20). Columns (1) and (7) show that the effect of the PSS on math and language is positive, statistically significant (at the $1 \%$ level), and higher for math than for language, when only the time trend $\left(\lambda_{t}\right)$ and the policy indicator $\left(w_{i t}\right)$ are considered. Despite the fact that the point estimate associated with math is higher than that for language, the trend coefficient associated with language is higher than that for math. This could be explained by specific reforms carried out to increase the quality of the language education content. As a result, SIMCE scores for language showed an increasing tendency attributable to curriculum reforms that were not implemented in math. Columns (2) and (3) and (8) and (9) show the estimated coefficients for math and language when family background is controlled for. After family income and the years of schooling of both parents are controlled for, the policy indicator is positive and statistically significant ( $1 \%$ ) and remains higher for math than for language.

The next three columns include the proportion of the EIP accomplished by schools in 2010 in math and language. This variable gives us an idea of how EIP reforms affect school performance. According to the model developed in section 3, in an environment of perfect competition, this variable should be statistically insignificant. Schools compete through quality, and the equilibrium education quality supplied to the market should be higher than the minimum required by the EIP. However, when some features of imperfect competition exist in the market, a higher minimum education quality required by the PSS contract should produce higher improvement in academic achievement in schools that join the PSS system. Therefore, if the Chilean education market is competitive, we expect that the coefficient of the policy indicator $w_{i t}$ ) is statistically different from zero but that the coefficient of the proportion of the EIP accomplished is statistically insignificant. The opposite conclusion is expected if the Chilean market is not competitive. Of course, a mix of results is also possible. A positive and significant
coefficient of the policy indicator and the proportion of the EIP accomplished should be a signal of a not fully competitive market where the EIP is, in some degree, binding with respect to the free-market equilibrium quality.

In all cases, the effect of the PSS on SIMCE scores, as well as the level of completion of the EIP, remains positive and significant (with exception of the policy indicator for language in column [12], which is not significant). According to results in column (6), if a school accomplished $100 \%$ of its math-specific goals proposed for 2010, its average SIMCE score would rise 4.7 points, in addition to the 2.6 -point increase associated with the policy indicator $\left(w_{i t}\right)$. For language, a full completion of the reforms implies, on average, 4.1 more points on SIMCE, in addition to the points attributable to the direct effect of the PSS on the school's academic performance (see column [12]).

An additional question is whether or not the PSS has a cumulative effect on school academic achievement, considering that, in our sample, all schools signed the agreement in 2009 and remained in the program until 2011. It is possible that the PSS has an additional effect for each additional year in the program. That lag in the effect of the PSS on academic achievement could exist for two reasons. First, it is possible that there are some adjustment costs. For instance, vouchers could increase competition for public schools and increase the margin per enrolled student for both public and voucher private schools. Both school types would have incentives to increase their quality. However, because of some adjustment costs (for instance, the construction of new infrastructure), the increase in quality would not materialize until some future period. Second, it is possible that students must be exposed to more than one period of investments in order to experience improvements in academic achievement.

Table 8 presents the results of equation (20), including the interaction of the policy indicator and the trend. By doing this, we capture the average effect of an additional year in the PSS on SIMCE scores. Columns (1) and (7) indicate that an additional year increases SIMCE by 1.5 points in math and 0.7 points in language, values that are statistically significant at the $1 \%$ level. After including school socioeconomic background variables (family income and parents' schooling), results remain positive and significant and are higher in math than in language. Moreover, when we include the percentage of EIP completion specific to each subject (columns [4]-[6] for math and [10]-[12] for language), our results indicate that each additional year of the PSS increases SIMCE scores by approximately 1.2 points in math and 0.33 points in language. Therefore, a school that has received PSS funds for three consecutive years and has completed all of the reforms proposed in its EIP by 2010 would increase its SIMCE score by 10 points in math and 5.6 points in language. To have an idea of the impact of the PSS, we can consider a school in the 50th percentile of the SIMCE score distribution-254 points in math and 264 in language. An increase of 10 points would place the school in the 66 th percentile in the math score distribution, while an increase of 5.6 points would put the school in the 59th percentile in the language score distribution. ${ }^{16}$

Tables 9 and 10 present the results of the same empirical models of tables 7 and 8 but only using a sample of voucher private schools. In general, we can observe that the coefficient on the policy indicator is slightly greater than in the model with both public and voucher

[^10]private schools. However, as discussed in section 3, a smaller coefficient was expected. That is because two channels (more competition and a greater margin per enrolled student) operate for public schools, but just one (a greater margin per enrolled student) operates for private schools. We interpret this result as preliminary evidence that public schools could face incentives and budget constraints that cause those types of schools to deviate from the profit-maximization goal. Sapelli (2003) shows that public schools are regulated by a Teaching Statute and receive additional funds from municipalities when necessary. Additionally, Hsieh and Urquiola (2006) show that despite extensive private entry and sustained declines in public enrollments, the aggregate number of municipal schools has barely fallen. Hsieh and Urquiola (2006) argue that municipal officials seem to have been unable or unwilling to close public schools, and, thus, public schools seem to not face strong incentives to compete. This is reinforced by the fact that, for these schools, revenue losses are mediated by municipal education budgets, which makes it possible for them to lose students without automatic consequences on their resources. The analysis in Sapelli (2003) and Hsieh and Urquiola (2006) could explain why the PSS has increased academic achievement in public schools, but not by the magnitude expected according to the theoretical analysis of section 3. However, overall, our results confirm the positive effects of vouchers on academic achievement and the importance of conditioning the delivery of resources to some specific academic goals when features of imperfect competition exist in the market.

Finally, notice that another testable implication of the model discussed in section 3 is that the effects of the PSS on academic achievement might be lower for schools receiving higher copayments. Table 11 presents the estimated coefficients of equation (20), including the interaction of the policy indicator and the shared financing made by parents. We conduct this exercise only for voucher private schools, considering that public schools are not allowed to charge any copayment to parents. Columns (1) to (12) show that, as our theoretical model predicts, the coefficient associated with the interaction is negative and statistically significant at the $1 \%$ level. This implies that the PSS increases academic achievement in voucher private schools that charge a lower co-payment more than in schools that receive a higher co-payment. Our theoretical model also predicts that schools that received a lower co-payment before 2008 have more incentive to enroll in the PSS program. Table 12 shows that, indeed, voucher private schools that enrolled in the PSS program charged a lower co-payment than did non-PSS schools before the introduction of the subsidy.

## 7 Conclusions

This paper provides empirical evidence of the effects of vouchers on the academic achievement of students. We focus on the Preferential Scholastic Subsidy (PSS) implemented in Chile in 2008. Different from the previous flat voucher system introduced in 1981, this new demand subsidy allows us to have a control group to evaluate the effects of the program. Our empirical strategy considers a difference-in-differences approach that allows us to remove the biases that result from the comparison of both groups in the second period and that can be explained by permanent differences between both groups and differences across time due to group-specific trends.

We find a positive effect of the PSS on standardized test scores. In an environment of perfect competition, the positive effect of vouchers on academic achievement operates mainly through two channels. First, the freedom of parents of low-income students to choose schools
introduces competition for public schools. Second, if the incidence of the demand subsidy (the voucher) on the supply of education is nonzero, vouchers (or an increase in the resources delivered by vouchers to schools) increase the margin per enrolled students (the difference between the total monetary payments and the cost of educating a student), which encourages schools to attract more students. If there is competition, education quality increases within both public and private schools through this second channel. Additionally, our results highlight the importance of conditioning the delivery of resources to some specific academic goals when features of imperfect competition exist in the market. Finally, we find a greater effect of the PSS when we consider only a sample of voucher private schools than when we include both public and voucher private schools. This result can be explained by the existence of "soft budget constraints" for public schools, which means that public schools do not face strong incentives to compete.

An interesting avenue for future research is related to the differential effects that the PSS had on math and language. That is, why did competition promote a higher supply of education quality in math than in language? One possible explanation is that parents value a scientific education relatively more than a humanistic education. Therefore, the demand for schools is more elastic to quality increases in scientific than in humanistic education. In this scenario, it is more effective for schools to increase the quality of their math education rather than their language education to attract more students. A formal empirical test of this hypothesis constitutes an interesting and important avenue to explore in the future.

Source: SIMCE 2006-2011 and Ministry of Education (Chile). Notes: (a) Gross family income corresponds to the average family income that students report at the
moment of taking SIMCE. It is expressed in thousands of Chilean pesos (CLP) for each one of the years considered in the sample (1 US\$ $=520$ CLP). (b) As we describe in the text, we include the proportion of the Educational Improvement Plan (EIP) accomplished by schools in 2010 in math and language. In 2010, schools under the PSS were visited by Ministry of Education personnel to determine the percentage of accomplishment of the measures defined in their EIP. (c) Shared financing corresponds to the interaction between the payment made by parents (in thousands of Chilean pesos) and the treatment variable ( $w_{i t}$ ). Standard errors in parentheses. ${ }^{* * *} \mathrm{p}<0.01$. ** $\mathrm{p}<0.05$. ${ }^{*} \mathrm{p}<0.1$.

Table 12: Shared Financing Charged by PSS and Non-PSS Schools (US\$)

| School Category | Mean | SD |
| :--- | :---: | :---: |
| PSS Schools | 26.2 | 41.1 |
| Non-PSS Schools | 66.2 | 17.1 |

[^12]
[^0]:    ${ }^{1}$ The SIMCE (Sistema de Medición de la Calidad de la Enseñanza) is a mandatory national standardized test designed to evaluate the quality of the content taught in primary and secondary education in math, language, geography, and science. It is administered annually to fourth, eighth, and tenth graders through a system in which grades are chosen to be evaluated by turns.

[^1]:    ${ }^{2}$ There are also studies on voucher programs that show how achievement growth among economically disadvantaged African-American children in U.S. cities rises if students are able to attend private schools instead of public schools. Howell and Peterson (2002) find evidence that African-American children benefit from access to private schools. Pooling African-American children at all grade levels, they find that private schooling enhances one- and two-year total achievement gains by 3.9 and 6.3 percentiles, respectively. Further, in New York and Washington, D.C., they find that the comparable three-year gain estimate is 6.6 percentiles.

[^2]:    ${ }^{3}$ Of course, this conclusion holds as long as the value of the PSS voucher received by public schools is greater than the cost of educating a vulnerable student.

[^3]:    ${ }^{4}$ Therefore, treatment and control schools are identical except by the fact that, after the PSS, the treatment schools face more competition (public schools) and receive a higher margin per enrolled student (public and voucher private schools).

[^4]:    ${ }^{5}$ At the beginning of 1980, more than $90 \%$ of all Chilean students were enrolled in institutions directly dependent on the Ministry of Education, and only the remaining $10 \%$ were enrolled in completely private institutions.

[^5]:    ${ }^{6}$ Subsidy law limited the family contribution to no more than US $\$ 153$ per month (in 2012 values).
    ${ }^{7}$ Public, voucher private schools, and private schools represented $40.71 \%, 50.73 \%$, and $8.56 \%$, respectively, of the total enrollment in primary and secondary education in 2010.

[^6]:    ${ }^{8}$ Depending on their performance on the SIMCE, schools could be classified as autonomous (if their performance is at or above the median for their SIMCE group), emergent (if their performance is below the median for their SIMCE group), or in recuperation (applied to emergent institutions that fail, after four years, to meet the quantitative goals required by the program).
    ${ }^{9}$ For instance, emergent schools receive half of their funding as a subsidy and the other half as a contribution of additional resources to design and execute their EIP, and schools that are in recuperation receive all of their funding as a contribution of additional resources to their EIP.
    ${ }^{10}$ In cases where selectivity is requisite, schools may not take into account past academic performance, current academic ability, or socioeconomic status.

[^7]:    ${ }^{11}$ Notice that $p^{* *}<p^{*}$.
    ${ }^{12}$ This conclusion is straightforward when we observe the equilibrium profits and the optimal choice of quality

[^8]:    ${ }^{13}$ As in the previous analysis, inequality (16) implies that all public schools subscribe to the PSS contract.

[^9]:    ${ }^{14}$ Moreover, an important assumption behind specification (20) is that changes in the trend are exclusively explained by (1) the treatment and/or (2) changes in the covariates that control for omitted school-specific trends.
    ${ }^{15}$ At the end of the four-year period, schools are evaluated on the basis of their performance on the SIMCE.

[^10]:    ${ }^{16}$ In additional regressions, we included dummy variables that equal 1 for PSS schools one and two years before the introduction of the PSS system. In this way, we test whether our results can be simply explained by schools that choose to be PSS receptors changing their behavior before signing the PSS contract. The conclusions do not change using this specification.
