

# Providing Advice to Job Seekers at Low Cost: An Experimental Study on On-Line Advice.

Michele Belot, Philipp Kircher, and Paul Muller\*

October 2015

## Abstract

Helping job seekers to identify suitable jobs is a key challenge for policy makers. We develop and evaluate experimentally a novel tool that provides tailored advice at low cost and thereby redesigns the process through which job seekers search for jobs. We invited 300 job seekers to our computer facilities for 12 consecutive weekly sessions. They searched for real jobs using our web interface. After 3 weeks, we introduced a manipulation of the interface for half of the sample: instead of relying on their own search criteria, we displayed relevant other occupations to them and the jobs that were available in these occupations. These suggestions were based on background information and readily available labor market data. We recorded search behavior on our site but also surveyed participants every week on their other search activities, applications and job interviews. We find that these suggestions broaden the set of jobs considered by the average participant. More importantly, we find that they are invited to significantly more job interviews. These effects are predominantly driven by job seekers who searched relatively narrowly initially and who have been unemployed for a few months.

**Keywords:** Online job search, occupational broadness, search design.

---

\**Affiliations:* Belot and Kircher, University of Edinburgh; Muller, VU Amsterdam and University of Gothenburg. This study was built on a research question proposed by Michele Belot. We thank the Job Centers in Edinburgh for their extensive support for this study, and especially Cheryl Kingstree who provided invaluable help and resources. We thank the Applications Division at the University of Edinburgh and in particular Jonathan Mayo for his dedication in programming the job search interface and databases, and to Peter Pratt for his consultation. We thank the UK Minister for Employment Mark Hoban as well as Tony Jolly at the UK Department for Work and Pensions Digital Services Division for granting us access to the vacancy data, and to Christopher Britton at Monster.com for liaising with us to provide technical access. We are grateful to Andrew Kelloe, Jonathan Horn, Robert Richards and Samantha Perussich for extensive research assistance and to Ivan Salter for managing the laboratory. We are thankful for the suggestions by seminar audiences at Field Days Rotterdam (2014), ESA Miami (2014), Workshop Economic Design and Institutions Brussels (2014), VU Amsterdam (2014), Experimental Methods in Policy Conference Cancun (2015), New York University Abu Dhabi (2015), CPB (2015), Newcastle Business School (2015), Annual conference of the RES (2015), IZA (2015), University of St Andrews (2015), Annual SaM conference Aix (2015), ESPE Izmir (2015), SED Warsaw (2015), Behavioural Insights Team (2015), NBER Summer Institute Boston (2015), EEA Meeting Mannheim (2015). We thank Christian Holzner for data on vacancy finding in Germany. Kircher acknowledges the generous financial support from European Research Council Grant No. 284119, without which this study would not have been possible. He thanks Jan van Ours for taking on the role of ethics adviser on this grant. The paper circulated previously under the title "Does Searching Broader Improve Job Prospects? - Evidence from variations of online search."

# 1 Introduction

Getting the unemployed back into work is an important policy agenda and a mandate for most employment agencies. In most countries, a main tool to achieve this is to impose requirements on benefit recipients to accept jobs beyond their occupation of previous employment, at least after a few months.<sup>1</sup> But little is said about how they should obtain such jobs, and how one might advise them in the process. Despite a substantial literature on the evaluation of active labor market policies, most studies confound advice with monitoring and sanctions. In his famous meta-study on active labor market policies, Card et al. (2010) merge “job search assistance or sanctions for failing to search” into one category.<sup>2</sup> Ashenfelter et al. (2005) assert a common problem that experimental designs “combine both work search verification *and* a system designed to teach workers how to search for jobs” and it is not clear which element is responsible for their documented success. Only few studies, reviewed in the literature section, have tried to fill the gap since, relying mostly on a mixture of labor-intensive counseling services.

Our study aims to contribute by providing a randomized study that offers targeted occupational advice to individual job seekers in a highly controlled and replicable low-cost environment. To our knowledge our study is the first to use the expanding area of online search to provide advice by re-designing the jobs search process on the web.

Internet-based job search is by now the predominant way of searching for jobs.<sup>3</sup> We asked professional programmers to set up two search platforms for internet-based job search. One “standard” platform where job seekers themselves decide which keywords and occupations to search for, similar to interfaces used on Universal Jobmatch (the official job search platform provided by the UK Department of Work and Pensions) and other commercial job search websites. The second “alternative” recommendation platform asks job seekers about the occupation they are looking for - which can coincide with the occupation of previous employment - and provides them with two lists containing the most related occupations. The first is based on common occupational transitions that similar people make and the second contains occupations for which skill requirements are similar. Job seekers can then simply hit the search button and are presented with all jobs in their geographic area that fall in any of these occupations. They can also take a look at maps to see where jobs are easier to find.

The benefits of such an intervention are that it provides job search advice in a highly controlled

---

<sup>1</sup>In an OECD paper, Venn (2012) outlines that the requirement to accept jobs from other occupations beyond the occupation of previous employment is one of the three main demands placed on the job search of benefit recipients (the others are geographical distance, and job search requirements during training). Countries differ by the length of time that benefit recipients can reject offers outside their occupation of previous employment: never (Australia, Denmark, Germany, Hungary, Ireland, Japan, New Zealand, Norway); no explicit time but dependent on previous work history (Canada, Czech Republic, Italy, Luxembourg, Poland, Slovak Republic, Sweden, Switzerland); less than six months (Austria, Estonia, Finland, France, Israel, Slovenia, United Kingdom, USA); more than six months (Belgium, Bulgaria, Cyprus, Malta, Netherlands, Spain); forever (Greece, Korea, Lithuania, Romania, Turkey). Like other labor market policies, there is substantial variation and disagreement of optimal policy across countries.

<sup>2</sup>See the clarification in Card et al. (2009), p. 6.

<sup>3</sup>Kuhn and Mansour (2014) document the wide use of the internet. Searchers who use the internet nowadays seem to be more effective than those who do not, contrary to findings at the turn of the millennium where this path was still relatively new and used by only a minority. In the UK where our study is based, roughly two thirds of job seekers (67%) and two thirds (64%) of employers now use the internet for search and recruiting (ONS (2013), Pollard et al. (2012)). In Germany, 2/3 of all vacancies that unemployed job seekers find are found through the internet (IAB (2010)).

manner based on readily available statistical information, entails only advice and no element of coercion (participants were free to continue with the “standard” interface if they wanted to), and constitutes a low-cost intervention. It allows us to tackle two questions. First, whether our implementation of advice changes how broad people search, where we define broadness as the average distance between occupational classification codes of the vacancies that are considered.<sup>4</sup> If it does, it allows us to investigate the second question whether the induced increase in occupational breadth increases job prospects. This is hard to assess without experimental variation because people who search broadly tend to differ also in other dimensions.

We report our overall impact on the treatment group relative to the control group. We also compare treatment and control in particular subgroups of obvious interest: our study has more scope to affect people who search narrowly prior to our intervention, and differential effects by duration of unemployment seem to be a major policy concern as mentioned in the introductory paragraph. Overall, we find that our intervention does expose job seekers to jobs from a broader set of occupations. And the number of job interviews increases, mainly in jobs outside the job seeker’s core occupation. This is driven predominantly by job seekers who otherwise search narrowly (compared to similarly narrow searchers in the control group). Among these, the effects are driven by those with above-median unemployment duration (more than 80 days). We take this as indication that increasing the breadth of search increases job prospects, and targeted job search assistance can be beneficial. It might not benefit everyone, though, and there is some (insignificant) indication that it might discourage those who otherwise already search broadly. We focus on job interviews as the number of jobs found are too limited to allow statistical inference.<sup>5</sup>

In terms of detail of our setup, a crucial obstacle in this type of experimental research is the two-sided nature of job markets: While one might rely on a limited number of job seekers for initial investigation, a realistic job search environment relies crucially on access to a large number of up-to-date vacancies. For this we convinced the largest UK job search platform, Universal Jobmatch run by the Department of Work and Pensions, to allow us access rights to its database of all live vacancies. Job seekers were recruited in Edinburgh and we transformed the experimental laboratory into a job search facility resembling those in “Employability Hubs” which provide computer access to job seekers throughout the city.<sup>6</sup> Participants were asked to search for jobs via our search platform from computers within our computer laboratory once a week for a duration of 12 weeks. The advantage of this “field-in-the-lab” approach is tight control along three dimensions: it ensures that job seekers indeed have access to a computer; any problems or questions with our new experimental platform

---

<sup>4</sup>The distance between two occupation codes is defined as zero when they are identical, 1 if they differ at the last digit, 2 if they differ at the second-to-last digit, up to 4 when they differ in all four digits. Alternative measures of broadness such as the Gini-Simpson index on a particular occupational digit provide similar qualitative results, independent of the digit we are using.

<sup>5</sup>Attrition from one week to the next is low in our study, ranging from 2% to 4% per week, but is of the same order of magnitude as the reported job findings, which are also low in the current economic climate. Since we do not know whether attrition is driven by those who find jobs and do not report back or those who simply drop out, inference is extremely difficult. In any case the numbers are too small to attribute statistical significance.

<sup>6</sup>Employability Hubs exist in several locations in Edinburgh through the cooperation Joined Up For Jobs comprising various non-for-profit organisations funded by the City of Edinburgh. They provide computer rooms for job seekers around Edinburgh. They also provide other advice services. While our setup is akin to their computer rooms, we never mentioned any connection while recruiting and we made clear that we do not provide any actual job search advice.

can be immediately handled; and participants' identities can be verified. The downside is a capacity restriction of 300 participants. As a twelve week panel this is a large number for experimental work but limited relative to usual labor market survey data. As a first experimental study on web-search design and advice we opted for more control and lower numbers.

All participants searched only with the "standard" interface for the first three weeks, which provides a baseline on how occupationally "broad" participants search in the absence of our intervention. Half of the participants continue with this interface throughout the study, while the other half was offered to try an "alternative" interface after the initial three weeks. The change was not previously announced, apart from a general introductory statement to all participants that included the possibility to alter the search engine over time. Instead of individual queries, our alternative interface asks individuals about desired occupation and geographic region, and then provides them at two clicks of a button with a list of alternative occupations (first click) and all vacancies that are within any of these occupations in the desired area (second click). This provides advice in a simple and intuitive way that can be applied to all individuals independent of their cognitive abilities. Obviously there is still room for the individual to make choices, both regarding which of the suggested jobs to consider in more detail and to apply for, as well as which desired occupation to name (which can be changed) and whether to deselect some proposed occupations. But the process is much more guided than the standard process where job seekers themselves have to come up with search terms.

There are two reasons to worry that the "recommendation" interface might have little effect. First, using it is not mandatory. Participants can opt to continue searching with the standard interface and, thus, they have to be willing to use the recommendation interface. All our results are reported independently of whether they use the interface or not (intention to treat) since all participants used the interface at least once and might have learned things that carry over even into their standard search activities. Nevertheless, low participation might lead to limited effects. Second, the information is taken from readily available sources and, therefore, might already be known to the participants or to their advisers at the job centre.

Yet we do find that our intervention is effective in increasing the breath of search and the number of job interviews, as mentioned earlier. We collect information both on search success when searching in our computer facilities and on success through other search channels. There is no crowding out between them. Both job interviews due to search within our computer lab increase as well as interviews obtained through other search channels, albeit only the sum is statistically significant. When we condition on those who search narrowly in the first three weeks, each of these measures of interviews increase significantly, indicating that the information that we provide on our interface affects their search positively not just exclusively on our platform. This is also the group for which we increase the occupational broadness of vacancy listings per week most relative to their peers in the control group (though we seem to decrease the geographical area they consider, possibly because they are now exposed to more suggestions within closer geographic proximity). Also the occupational broadness of the jobs to which they apply increases, although insignificantly, and their number of applications increases significantly. The increase in the number of job interviews is particularly strong for those who search occupationally narrow and have above median unemployment duration.

While it is straightforward why our information intervention has more scope to broaden the perspective for individuals who otherwise search narrowly, it might be less obvious why our effects are larger for those individuals with slightly longer unemployment duration. A simple learning theory - which we advance theoretically in a later section - can rationally account for this behaviour. If individuals who lost their jobs deem it quite likely that they will obtain a job again in the same profession, searching for jobs in this occupation might dominate search in alternative occupations (i.e., they search narrowly). If the perceived difference between occupations is large, the alternative occupations remain dominated even after we provide positive information on some of them. After a few months, unsuccessful individuals learn that their chances in their occupation of previous employment are lower than expected, and the perceived difference with other occupations shrinks. Now alternative suggestions can render the endorsed occupations attractive enough to be considered. Our intervention induces search over a larger set of occupations and increases the number of interviews. One can contrast this with the impact on individuals who already search broadly because they find many occupations roughly equally attractive. They can rationally infer that the occupations that we do not endorse are less suitable, and they stop applying there to conserve search effort. Their broadness declines, but effects on job interviews are theoretically ambiguous because search effort decreases but is better targeted. In the data it is indeed the case that initially broad individuals in the treatment group become occupationally narrower than comparable peers in the control group, but effects on job finding are insignificant.

Our findings suggest concrete policy recommendations: targeted web-based advice might be helpful to job seekers. This is particularly interesting because interventions such as the one we evaluate have essentially zero marginal costs, and could be rolled out on large scale without much burden on the unemployment assistance system.<sup>7</sup>

Clearly these results need to be viewed with caution. Evidence on job finding probabilities are not conclusive given our limited sample size. Even if these were conclusive, a true cost-benefit analysis would need to take into account whether additional jobs are of similar quality (e.g. pay similarly and can be retained for similar amounts of time). Such analysis is desirable, but requires a larger sample size with longer follow-up, ideally based on access to administrative data. Larger roll-out in different geographic areas would also be needed to uncover any general equilibrium effects, which could reduce the effectiveness if improved search by some job seekers negatively affects others, or could boost the effectiveness if firms react to more efficient search with more job creation. We hope that future research in conjunction with conventional large-scale operators of job search platforms will marry the benefits of our approach with their large sample sizes.

The subsequent section reviews the related literature. Section 3 outlines the institutional environment. Section 4 describes the experimental design, Section 5 the basics of our sample, and Section 6 our empirical analysis and findings. Section 7 uses a simple model to illustrate the forces that might underlie our findings, and the final section concludes.

---

<sup>7</sup> The study itself cost roughly £100000, of which the largest part was compensation to participants, costs of programming, and salaries for research assistants. Designing the "recommendation" platform only cost a fraction, and once this is programmed, rolling it out more broadly would have no further marginal cost of an existing platform such as Universal Jobmatch. Obviously, for researchers without an existing client base, the marginal cost of attracting an additional participant to the study/website in the first place is nontrivial.

## 2 Related Literature

The idea that search over different occupations is important in the job search process has a long tradition both in the applied micro and in the macro-labor literature.<sup>8</sup> But as argued in the introductory paragraph, there are few experimental studies that focus exclusively on providing advice, which limits our knowledge on the effectiveness of information interventions in the labor market.<sup>9</sup>

Prior to our study the main focus of experimental investigation has been the provision of counseling services by traditional government agencies and by new entrants from the private sector. Behaghel et al. (2014) and Krug and Stephan (2013) provide evidence from France and Germany that public counselling services are effective and outperform private sector service provision, while Bennmarker et al. (2009) finds similar overall effectiveness of the private and public counseling services in Sweden with differential performance among specific subgroups. There are indications that more advice would also be beneficial in the UK.<sup>10</sup> General equilibrium effects are investigated in Crepon et al. (2013), who analyze a large scale rollout of private sector counseling in France. While they cannot demonstrate such effects with statistical significance, the point estimates on the effectiveness of counselling services reduces to zero when general equilibrium effects are accounted for. The upshot of these studies is their scale and the access to administrative data to assess their effects. The downside is the large costs that range from several hundred to a few thousand Euro per treated individual, and the "black box" of how advice is actually provided to individuals and how it affects their job search. This complicates replication in other settings. Our study can be viewed as complementary. It involves nearly zero marginal cost, the type of advice is clearly focused on occupational information, it is standardized, its internet-based nature makes it easy to replicate, and the detailed data on actual job search allow us to study the effects not only on outcomes but also on the search process. Yet we have a small and geographically confined set of participants and limited outcome measures.

Contemporaneously, Altmann et al. (2015) analyze the effects of a brochure that they sent to a

---

<sup>8</sup>For example, Miller (1984), Neal (1999), Gibbons and Waldman (1999), Gibbons et al. (2005), Papageorgiou (2014) and Groes et al. (2015) document occupational mobility consistent with learning about occupational skills. Moscarini and Thomsson (2007) and Kambourov and Manovskii (2008) highlight the high degree of occupational turnover in the US. Among others, Kambourov and Manovskii (2009) and Carrillo-Tudela and Visschers (2014) consider mobility and wage dynamics under occupation-specific skills and occupation-specific shocks. Barnichon and Figura (2014) and Sahin et al. (2014) point out that unequal market tightnesses across geography and occupations can contribute to overall aggregate unemployment, which opens the possibility that more balanced search can reduce aggregate unemployment.

<sup>9</sup>Ashenfelter et al. (2005) apply indirect inference to ascertain the effectiveness of job search advice. They start by citing experimental studies from the US by Meyer (1995) which have been successful but entailed monitoring/sanctions as well as advice. Ashenfelter et al. (2005) then provide evidence from other interventions that monitoring/sanctions are ineffective in isolation. Indirect inference then attributes the effectiveness of the first set of interventions to the advice. Yet subsequent research on the effects of sanctions found conflicting evidence: e.g., Micklewright and Nagy (2010) and Van den Berg and Van der Klaauw (2006) also find only limited effects of increased monitoring, while other studies such as Van der Klaauw and Van Ours (2013), Lalive et al. (2005) and Svarer (2011) find strong effects.

<sup>10</sup>Fieldwork by the UK government's Behavioral Insights Team finds indications "that many claimants' first contact with the job centre focused entirely on claiming benefits, and not on finding work" (Gallagher et al. (2015)). This opens up the possibility that advice can indeed improve the search outcomes even here. Gallagher et al. (2015) themselves undertake a randomized trial. This trial includes many elements including advice but also monitoring/sanctions: it re-focuses the initial meeting on search planning, introduces goal-setting and monitoring, and includes resilience building through creative writing. They find positive effects of their intervention, but cannot attribute it to the various elements. The resembles findings by Launov and Waelde (2013) that attribute the success of German labor market reforms to service restructuring (again both advice and sanctions) rather than benefit reductions. Another study for the UK conducted by Blundell et al. (2004) evaluates the "New Deal for the Young Unemployed". It provided job search assistance but it also included other elements, most notably a wage subsidy to unemployed youth.

large number of randomly selected job seekers in Germany, containing a paragraph of information and motivation on each of the following dimensions: i) labor market conditions, ii) duration dependence, iii) effects of unemployment on life satisfaction, and iv) importance of social ties. For this bundle, they find no significant effect overall, but for those at risk of long-term unemployment they find a positive effect between 8 months and a year after the brochure was sent. In our intervention we find effects overall but also especially for individuals with longer unemployment duration, even though we assess the intervention much closer in time to the actual information provision. Their study has low costs of provision, is easily replicable, treated a large sample, and has administrative data to assess success. On the other hand, it is not clear which of the varied elements in the brochure drives the results, there are no intermediate measures on how it affects the job search process, and the advice is generic to all job seekers rather than specific to the occupations they are looking for.

Our study is also complementary to a few recent studies which study data from commercial online job boards. It commenced with pioneering work on employer behavior by Kuhn and Shen (2013b), but recent studies cited below shift attention to job search behavior which is also the focus of our study.<sup>11</sup> Their great advantage is the large amount of data that is available. They have not investigated the role of advice, though, nor can they rely on experimental variation. Another downside is a lack of information about which other channels job seekers are using to search for jobs and why they are leaving the site.<sup>12</sup> We improve on the latter dimensions through our randomized design and the collection of data on other search channels, albeit at the cost of a comparatively small sample size.

Kudlyak et al. (2014) analyze U.S. data from Snagajob.com and find that job search is stratified by educational attainment but that job seekers lower their aspirations over time. Using the same data source, Faberman and Kudlyak (2014) investigate whether the declining hazard rate of finding a job is driven by declining search effort. They find little evidence for this. The data lacks some basic information such as employment/unemployment status and reason for leaving the site, but they document some patterns related to our study: Occupational job search is highly concentrated and absent any exogenous intervention it broadens only slowly over time, with 60% of applications going to the modal occupation in week 2 and still 55% going to the modal occupation after six months.

Marinescu and Rathelot (2014) investigate the role of differences in market tightness as a driver of aggregate unemployment. They discipline the geographic broadness of search by using U.S search data from Careerbuilder.com. They concur with earlier work that differences in market tightness are not a large source of unemployment. This holds even in a robustness check that also allows for occupational segregation at the 2-digit code level. In their dataset search is rather concentrated, with the majority of applications aimed at jobs within 25km distance and 82% of applications staying in

---

<sup>11</sup>Kuhn and Shen (2013b) investigate explicit gender discrimination in an environment where this is legal by looking at online data from Chinese job boards, and documents that many job advertisements are explicitly gender-specific. Hellester et al. (2014) extend this analysis to additional datasets from China and Mexico. Kuhn and Shen (2013a) document for a Chinese website that firms are reluctant to hire overqualified workers.

<sup>12</sup>Information on other search channels might be important if one is worried that effects on any one search channel might simply be shifts away from other search channels. Van den Berg and Van der Klaauw (2006) highlight this as the main reason for the ineffectiveness of monitoring the search activities of job seekers, since it mainly shifts activities out of hard-to-observe search channels like contacting family and friends into easy-to-observe search channels such as writing formal job applications. For our non-coercive information intervention we do not find such crowding out.

the same city (Core-Based Statistical Area), even if some 10% go to distances beyond 100km.<sup>13</sup> Using the same data source, Marinescu (2014) investigates equilibrium effects of unemployment insurance by exploiting state-level variation of unemployment benefits. The level of benefits affects the number of applications, but effects on the number of vacancies and overall unemployment are limited. Marinescu and Wolthoff (2014) document that job titles are an important explanatory variable for attracting applications in Careerbuilder.com, that they are informative above and beyond wage and occupational information, and that controlling for job titles is important to understand the remaining role of wages in the job matching process. As mentioned, none of these studies involve a randomized design.

To our knowledge, this is the first paper that undertakes job-search platform design and evaluates it. The randomized setup allows for clear inference. While the rise in electronic search will render such studies more and more relevant, the only other study of search platform design that we are aware of is Dinerstein et al. (2014), who study a change at the online consumer platform Ebay which changed the presentation of its search results to order it more by price relative to other characteristics. This led to a decline in prices, which is assessed in a consumer search framework. While similar in broad spirit of search design, the studies obviously differ substantially in focus.

### 3 Institutional Setting

We describe briefly the institutional settings relevant for job seekers in the UK during the study. Once unemployed, a job seeker can apply for benefits (Job Seekers Allowance, JSA), by visiting their local job centre. If they have contributed sufficiently through previous employment, they are eligible for contribution-based JSA, which is £56.25 per week for those aged up to age 24, and £72 per week for those aged 25 and older. These benefits last for a maximum of 6 months. Afterwards - or in the absence of sufficient contributions - income-based JSA applies, with identical weekly benefits but with extra requirements. The amount is reduced if they have other sources of income, if they have savings or if their partner has income. Once receiving JSA, the recipient is not eligible for income assistance, however they may receive other benefits such as housing benefits.

JSA recipients should be available and actively looking for a job. In practice, this implies committing to agreements made with a work coach at the job centre, such as meeting the coach regularly, applying to suggested vacancies, participating in suggested training. The work coach can impose sanctions on benefit payments in case of non-compliance to any of the criteria.

In Figure 1 we present aggregate labor market statistics. In particular, figure (a) shows the unemployment rate in the UK and Edinburgh since 2011. The vertical line indicates the start of our study. The unemployment rate in Edinburgh is slightly lower than the UK average, and is rather stable between 2011 and 2014. These statistics are based on the Labour Force Survey and may therefore be less precise. Therefore we present the number of JSA claimants in the Edinburgh and the UK in panel (b), which is an administrative figure and should be strongly correlated with unemployment. We find

---

<sup>13</sup>These numbers are based on Figure 5 in the 2013 working paper. Neither paper provides numbers on the breadth of occupational search. The "distaste" for geographical distance backed out in this work for the US is lower than that backed out by Manning and Petrongolo (2011) from more conventional labor market data in the UK, suggesting that labor markets in the UK are even more local.

that the number of JSA claimants is decreasing monotonically between 2012 and 2015, and that the Edinburgh and UK figures follow a very similar path. The number of JSA claimants in Edinburgh during our study is approximately 9,000, such that the 150 participants per wave in our study are about 2% of the stock. The monthly flow of new JSA claimants in Edinburgh during the study is around 1,800 (not shown in the graph).

Figure 1: Aggregate labor market statistics

## 4 Experimental Design

### 4.1 Basic setup

We conducted the study in the computer facilities of the School of Economics at the University of Edinburgh over the course of the academic year 2013-14. Unemployed job seekers were invited to search for jobs in our computer laboratory once a week for a period of 12 weeks, or until they found a job. The study consisted of two waves: wave 1 started in September 2013 and wave 2 started in January 2014. We conducted sessions at six different time slots, on Mondays or Tuesdays at 10 am, 1 pm or 3:30 pm. Participants chose a slot at the time of recruitment and were asked to keep the same time slot for the twelve consecutive weeks.

Participants were asked to search for jobs using our job search engine (described later in this section) for a minimum of 30 minutes.<sup>14</sup> After this period they could continue to search or use the computers for other purposes such as writing emails, updating their CV, or applying for jobs. They

<sup>14</sup>The 30 minute minimum was chosen as a trade-off between on the one hand minimizing the effect of participation on the natural amount of job search, while on the other hand ensuring that we obtained enough information. Given that participants spent around 12 hours a week on job search, a minimum of half an hour per week is unlikely to be a binding constraint on weekly job search, while it was a sufficient duration for us to collect data. Furthermore, similar to our lab participants, the participants in the online survey (who did not come to the lab and had no restrictions on how much to search) also indicate that they search 12 hours per week on average. Among this group, only in 5% of the cases the reported weekly search time is smaller than 30 minutes. In the study, the median time spent in the laboratory was 46 minutes. We made sure that participants understood that this is not an expectation of their weekly search time, and that they should feel free to search more and on different channels.

Table 1: Recruitment and show-up of participants

	Full sample	Wave 1	Wave2
Recruitment channel participants:			
Job centres	86%	83%	89%
Gumtree or other	14%	17%	11%
Sign up rate jobcentre for lab study <sup>a</sup>	43%	39%	47% <sup>c</sup>
Show up rate lab study	45%	43%	46%
Sign up rate jobcentre for online study <sup>a</sup>		60%	
Show up rate online study <sup>b</sup>	21%	21%	21%

<sup>a</sup> Of those people that were willing to talk to us about the study, this is the share that signed up for the study. <sup>b</sup> About a fourth of those that signed up for the online study had a non-existing email address, which partly explains the low show up rate.

<sup>c</sup> Based on only one day of recruitment (see footnote 19).

could stay in our facility for up to two hours. We emphasized that no additional job search support or coaching would be offered.

All participants received a compensation of £11 per session attended (corresponding to the government authorized compensation for meal and travel expenses) and we provided an additional £50 clothing voucher for job market attire for participating in 4 sessions in a row.<sup>15</sup>

## 4.2 Recruitment Procedure and Experimental Sample

We recruited job seekers in the area of Edinburgh. The eligibility criteria for participating to the study were: being unemployed, searching for a job for less than 12 weeks (a criterion that we did not enforce), and being above 18 years old.<sup>16</sup> We imposed no further restrictions in terms of nationality, gender, age or ethnicity.

We obtained the collaboration of several local public unemployment agencies (Jobcentres) to recruit job seekers on their premises. Their counsellors were informed of our study and were asked to advertise the study. We also placed posters and advertisements at various public places in Edinburgh (including libraries and cafes) and posted a classified ad on a popular on-line platform (not limited to job advertisements) called Gumtree. In Table 1 sign up and show up rates are presented. Of all participants, 86% were recruited in the Jobcentres. Most of the other participants were recruited through our ad on Gumtree. We approached all visitors at the Jobcentres during two weeks.<sup>17</sup> Out of those we could talk to and who did not indicate ineligibility, 43% percent signed up. Out of everyone that signed up, 45% showed up in the first week and participated in the study. These figures display no statistically significant difference between the two waves of the study.

We also conducted an online study, in which job seekers were asked to complete a weekly survey

<sup>15</sup>All forms of compensation effectively consisted of subsidies, i.e. they had no effect on the allowances the job seekers were entitled to. The nature and level of the compensation were discussed with the local job centres to be in accordance with the UK regulations of job seeker allowances.

<sup>16</sup>We do drop the observations on one participant from our sample because this participant had been unemployed for over 30 years and was therefore an extraordinary outlier in our sample.

<sup>17</sup>Since most Job Seekers Allowance recipients were required to meet with a case worker once every two weeks at the Jobcentre, we were able to approach a large share of all job seekers.

about their job search. These participants did not attend any sessions, but simply completed the survey for 12 consecutive weeks. This provides us with descriptive statistics about job search behavior of job seekers in Edinburgh and it allows us to compare the online participants with the lab participants. These participants received a £20 clothing voucher for each 4 weeks in which they completed the survey. The online participants were recruited in a similar manner as the lab participants, which means most of them signed up at the Jobcentres.<sup>18</sup> The sign up rate at the Jobcentres was slightly higher for the online survey (58%), however out of those that signed up, only 21% completed the first survey. This was partly caused by the fact that about one-fourth of the email addresses that were provided was not active.<sup>19</sup>

In section 5.1 we discuss in more detail the representativeness of the sample, by comparing the online and the lab participants with population statistics.

### 4.3 Study Procedure

Participants were asked to register in a dedicated office at the beginning of each session. At the first session, they received a unique username and password and were told to sit at one of the computer desks in the computer laboratory. The computer laboratory was the experimental laboratory located at the School of Economics at the University of Edinburgh with panels separating desks to minimize interactions between job seekers. They received a document describing the study as well as a consent form that we collected before the start of the initial session (the form can be found in the Online Appendix OA.1). We handed out instructions on how to use the interface, which we also read aloud (the instructions can be found in the Online Appendix OA.2). We always had assistance in the laboratory to answer questions. We clarified that we were unable to provide any specific help for their job search, and explicitly asked them to search as they normally would.

Once they logged in, they were automatically directed to our own website.<sup>20</sup> They were first asked to fill in a survey. The initial survey asked about basic demographics, employment and unemployment histories as well as beliefs and perceptions about employment prospects. From week 2 onwards, they only had to complete a short weekly survey asking about job search activities and outcomes. For vacancies saved in their search in our facility we asked about the status (applied, interviewed, job offered). We asked similar questions about their search through other channels than our study. The weekly survey also asked participants to indicate the extent to which they had personal, financial or health concerns (on a scale from 1 to 10). The complete survey questionnaires can be found in the Online Appendix OA.4.

After completing the survey, the participants were re-directed towards our search engine and could start searching. A timer located on top of the screen indicated how much time they had been searching.

---

<sup>18</sup>Participants were informed of only one of the two studies, either the on-site study or the on-line study. They did not self-select into one or the other.

<sup>19</sup> We asked the recruiters to write down the number of people they talked to and the number that signed up. Unfortunately these have not been separated for the online study and the lab study. In the first wave there were different recruiters for the two studies, such that we can compute the sign up shares separately. In the second wave we asked assistants to spend parts of their time per day exclusively on the lab study and parts exclusively on the online study, so we only have sign-ups for the total number. One day was an exception, as recruitment was done only for the lab study on this day, such that we can report a separate percentage based on this day.

<sup>20</sup>[www.jobsearchstudy.ed.ac.uk](http://www.jobsearchstudy.ed.ac.uk)

Once the 30 minutes were over, they could end the session. They would then see a list of all the vacancies they had saved and were offered the option of printing these saved vacancies. This list of printed vacancies could be used as evidence of required job search activity at the Jobcentre. It was, however, up to the job seekers to decide whether they wanted to provide that evidence or not. We also received no additional information about the search activities or search outcomes from the Jobcentres. We only received information from the job seekers themselves. This absence of linkage was important to ensure that job seekers did not feel that their search activity in our laboratory was monitored by the employment agency. They could then leave the facilities and receive their weekly compensation.<sup>21</sup> Those who stayed could either keep searching with our job search engine or use the computer for other purposes (such as updating their CV, applying on-line or using other job search engines). We did not keep track of these other activities. Once participants left the facility, they could still access our website from home, for example in order to apply for the jobs they had found.

## 4.4 Experimental Treatments

We introduce experimental variation through changes in the job search engine. All participants started using a “standard” search interface. Then from week four onwards half of the participants were allocated an “alternative” search interface which provided recommendations of alternative occupations in which they could search for jobs. We now explain in more detail how each of these interfaces work, and how we assigned them.

### 4.4.1 The Standard Interface

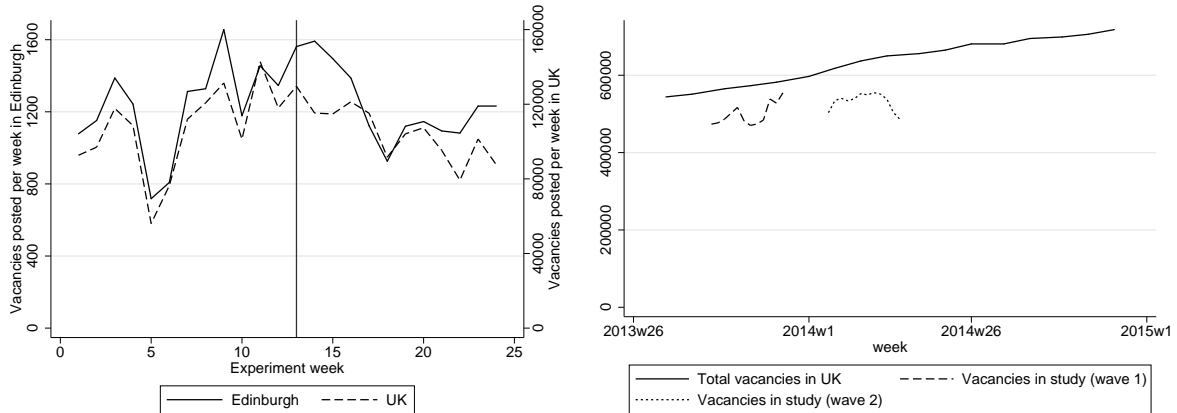

We designed a job search engine in collaboration with the computer applications team at the University of Edinburgh. It was designed to replicate the search options available at the most popular search engines in the UK (such as monster.com and Universal Jobmatch), but allowing us to record precise information about how people search for jobs (what criteria they use, how many searches they perform, what vacancies they click on and what vacancies they save), as well as collecting weekly information (via the weekly survey) about outcomes of applications and search activities outside the laboratory.

The search engine uses a database of real job vacancies, which is identical to those provided on the government website Universal Jobmatch. This is the largest in the UK in terms of the number of vacancies. This is a crucial aspect in the setup of the study, because results can only be trusted to resemble natural job search if participants use the lab sessions for their actual job search. The large set of available vacancies combined with our carefully designed job search engine assures that the setting was as realistic as possible. Panel (a) of Figure 2 shows the number of posted vacancies available through our search engine in Edinburgh and in the UK for each week of the study (the vertical line indicates the start of wave 2). Each week there are between 800 and 1600 new vacancies posted in the Edinburgh. Furthermore, there is strong correlation between vacancy posting in Edinburgh and the UK. In panel (b) the total number of active vacancies in the UK is shown over the second half of 2013

---

<sup>21</sup>Participants were of course allowed to leave at any point in time but they were only eligible to receive the weekly compensation if they had spent 30 minutes searching for jobs using our search engine.

Figure 2: Number of vacancies

(a) Posted vacancies in our study

(b) Active vacancies in our study and in UK

and 2014.<sup>22</sup> As a comparison the total number of active vacancies in the database used in the study in both waves is shown. It suggests that the database contains over 80% of all UK vacancies, which is a very extensive coverage compared to other online platforms.<sup>23</sup> It is well-known that not all vacancies on online job search platforms are genuine, so the actual number might be somewhat lower.<sup>24</sup> We introduced ourselves a small number of “fake” vacancies (about 2% of the database) for a separate research question (addressed in a separate paper). Participants were fully informed about this. They were told that “we introduced a number of vacancies (about 2% of the database) for research purposes to learn whether they would find these vacancies attractive and would consider applying to them if they were available”.<sup>25</sup> This small number is unlikely to affect job search, and there is no indication of differential effects by treatment group.<sup>26</sup>

Figure 3 shows a screenshot of the main page of the standard search interface. Participants can search using various criteria (keywords, occupations, location, salary, preferred hours), but do not have to specify all of these. Once they have defined their search criteria, they can press the search

<sup>22</sup>Panel (b) is based on data from our study and data from the Vacancy Survey of the Office of National Statistics (ONS), dataset “Claimant Count and Vacancies - Vacancies”, url: [www.ons.gov.uk/ons/rel/lms/labour-market-statistics/march-2015/table-vacs01.xls](http://www.ons.gov.uk/ons/rel/lms/labour-market-statistics/march-2015/table-vacs01.xls)

<sup>23</sup>For comparison, the largest US jobsearch platform has 35% of the official vacancies; see Marinescu (2014), Marinescu and Wolthoff (2014) and Marinescu and Rathelot (2014). The size difference might be due to the fact that the UK platform is run by the UK government.

<sup>24</sup> For Universal Jobmatch evidence has been reported on fake vacancies covering 2% of the stock posted by a single account (Channel 4 (2014)) and speculations of higher total numbers of fake jobs circulate (Computer Business Review (2014)). Fishing for CV’s and potential scams are common on many sites, including Careerbuilder.com (The New York Times (2009a)) and Craigslist, whose chief executive, Jim Buckmaster, is reported to say that “it is virtually impossible to keep every scam from traversing an Internet site that 50 million people are using each month” (The New York Times (2009b)).

<sup>25</sup>Participants were asked for consent to this small percentage of research vacancies. They were informed about the true nature of such vacancies if they expressed interest in the vacancy before any actual application costs were incurred, so any impact was minimized. We exploit this experimental variation in vacancy postings in a separate paper.

<sup>26</sup>In an exit survey the vast majority of participants (86%) said that this did not affect their search behavior, and this percentage is not statistically different in the treatment and control group (p-value 0.99). This is likely due to the very low numbers of fake vacancies and to the fact that fake advertisements are common in any case to online job search sites (see footnote 24) and that this is mentioned to job seekers in many search guidelines (see e.g. Joyce (2015)).

Figure 3: Standard search interface

button at the bottom of the screen and a list of vacancies fitting their criteria will appear. The information appearing on the listing is the posting date, the title of the job, the company name, the salary (if specified) and the location. They can then click on each individual vacancy to reveal more information. Next, they can either choose to “save the job” (if interested in applying) or “do not save the job” (if not interested). If they choose not to save the job, they are asked to indicate why they are not interested in the job from a list of possible answers.

As in most job search engines, they can modify their search criteria at any point and launch a new search. Participants had access to their profile and saved vacancies at any point in time outside the laboratory, using their login details. They could also use the search engine outside the laboratory. We recorded all search activity taking place outside the lab. This is however only a very small share compared to the search activities performed in the lab.

#### 4.4.2 The Alternative Interface

We designed an alternative interface again in collaboration with the Applications team at the University of Edinburgh. This interface aims to reduce informational frictions and to expose job seekers to the set of vacancies that is likely to be relevant to them. The interface consists of two alterations. First, based on their profile it suggests possible occupations job seekers may be suited for. Second, it provides visual information on the tightness of the labor market for broad occupational categories in regions in Scotland. Furthermore, the search engine was somewhat restricted in the criteria that could be specified (it only allows to use occupation and radius as search criteria).

When using the alternative interface, participants were asked to specify their preferred occupation. They could change their preferred occupation at any time over the course of the study. The

preferred occupation was then matched to a list of possibly suitable occupations using two different methodologies. The first uses information from the British Household Panel Survey and from the national statistical database of Denmark (because of larger sample size).<sup>27</sup> Both databases follow workers over time and record in what occupation they are employed. We then match the indicated preferred occupation to the most common occupations to which people employed in the preferred occupation transition to.<sup>28</sup>

The second methodology uses information on transferable skills across occupations from the US based website O\*net, which is an online “career exploration” tool sponsored by the US department of Labor, Employment & Training Administration. For each occupation, they suggest up to 10 related occupations that require similar skills. We retrieved the related occupations and presented the ones related to the preferred occupation as specified by the participant.

Once participants have specified their preferred occupation, they could then click “Save and Start Searching” and were taken to a new screen where a list of suggested occupations was displayed. The occupations were listed in two columns: The left column suggests occupations based on the first methodology (based on labor market transitions). The right column suggests occupations based on the second methodology (O\*net related occupations). Figure 4 shows the alternative interface, with suggestions based on the preferred occupation ‘cleaner’. Participants were fully informed of the process by which these suggestions came about, and could select or unselect the occupations they wanted to include or exclude in their search. By default all were selected. If they then click the “search” button, the program searches through the same underlying vacancy data as in the control group but selects all vacancies that fit any of the selected occupations.<sup>29</sup>

We also provided information about how competitive the labor market is for a given set of occupations. We constructed “heat maps” that use recent labor market statistics for Scotland and indicate visually (with a colored scheme) where jobs may be easier to get (because there are many jobs relative to the number of interested job seekers). These maps were created for each broad occupational category (two-digit SOC codes).<sup>30</sup> Participants could access the heat maps by clicking on the button “heat map” which was available for each of the suggested occupations based on labor market transitions. So they could check them for each broad category before actually performing a search, not for each particular vacancy.

---

<sup>27</sup>The name of the database is IDA - Integrated Database for Labour Market Research administered by Statistics Denmark. We are grateful to Fayne Goes for providing us with the information.

<sup>28</sup>For each occupation we created a list of the 3 to 5 most common transitions; at least 3 if available and at most 5 if more than 5 were available. These consist of occupations that are in both datasets in the top-10 common transitions. If there are less than 3 of these, we added the most common transitions from each of the datasets.

<sup>29</sup>Occupations in O\*net have a different coding and description and have a much finer categorization than the three-digit occupational code available in the British Household Panel Survey (BHPS) and in Universal Jobmatch vacancy data. We therefore asked participants twice for their preferred occupation, once in O\*net form and BHPS form. The query on the underlying database relies on keyword search, taking the selected occupations as keywords, to circumvent problems of differential coding.

<sup>30</sup>These heat maps are based on statistics provided by the Office for National Statistics, (NOMIS, claimant count, by occupations and county, see <https://www.nomisweb.co.uk/>). We created the heat maps at the two-digit level because data was only available on this level. Clearly, this implies that the same map is offered for many different 4-digit occupations, and job seekers might see the same map several times. Obviously a commercial job search site could give much richer information on the number of vacancies posted in a geographic area and the number of people looking for particular occupations in particular areas. An example of one of the heat maps is presented in the Online Appendix OA.5.

Figure 4: Alternative interface (for preferred occupation 'cleaner')

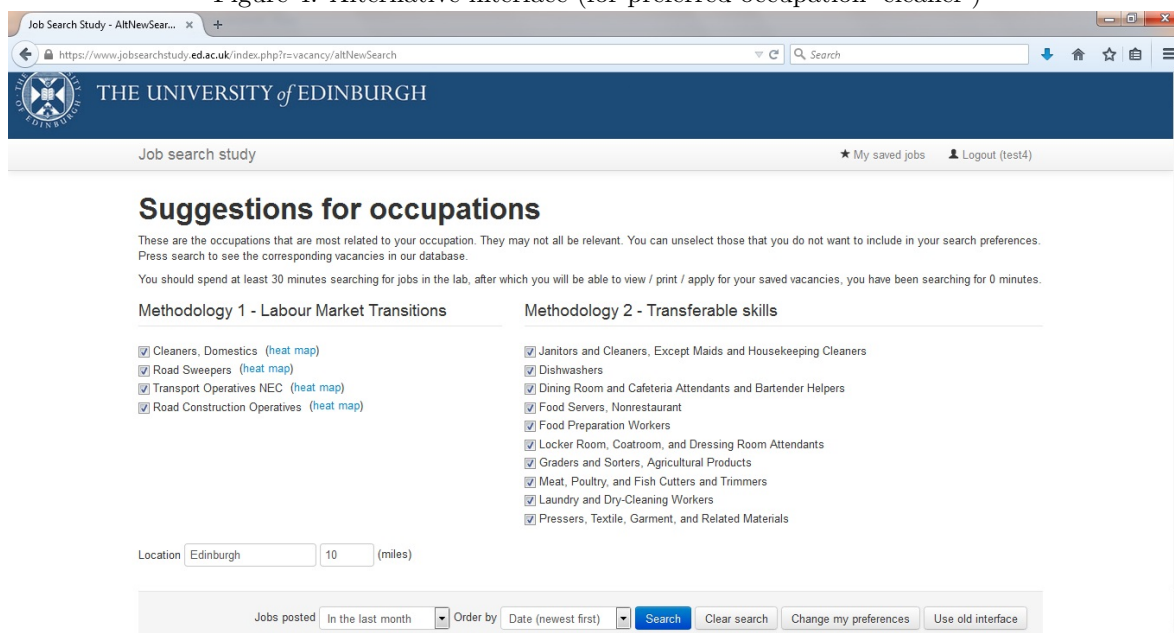

Table 2: Randomization scheme

	Wave 1	Wave 2
Monday 10 am	Control	Treatment
Monday 1 pm	Treatment	Control
Monday 3:30 pm	Control	Treatment
Tuesday 10 am	Treatment	Control
Tuesday 1 pm	Control	Treatment
Tuesday 3:30 pm	Treatment	Control

Participants in the treatment group received a written and verbal instruction of the alternative interface (see Online Appendix OA.3), including how the alternative recommendations were constructed, in the fourth week of the study before starting their search. For them, the new interface became the default option when logging on. It should be noted, though, that it was made clear to participants that using the new interface was not mandatory. Rather, they could switch back to the previous interface by clicking a button on the screen indicating “use old interface”. If they switched back to the old interface, they could carry on searching as in the previous weeks. They could switch back and forth between new and old interface. This ensures that we are not restricting choice, but rather offer advice.

#### 4.4.3 Randomization

From week 4 onwards, we changed the search interface to the alternative interface for a subset of our sample. Participants were randomized into control (no change in interface) and treatment group (alternative interface) based on their allocated time slot. We randomized each time slot into treatment and control over the two waves, to avoid any correlation between treatment status and a particular time slot. Table 2 illustrates the randomization.

## 5 Background Data on our Sample

### 5.1 Representativeness of the sample

Since the participants were not randomly selected from the population of job seekers in Edinburgh, one may worry that the sample consists of a selective group that differs from the general population. To provide some indication of the degree of selection, we compare characteristics of the participants to the online survey participants, and to aggregate statistics of job seekers available from The Office of National Statistics (NOMIS). These descriptive statistics are presented in Table 3. The first four columns show the mean, standard deviation, minimum and maximum for the lab participants, while the next four columns show the same statistics for the online survey participants. In column 9, the p-value of a two-sided t-test for equal means is shown. Finally, in column 10 aggregate statistics of job seekers in Edinburgh are shown, for the variables for which these are available.<sup>31</sup>

Demographic variables, based on the first week baseline survey, show that 43% of the lab participants are female, the average age is 36 and 43% have some university degree. 80% classify themselves as ‘white’ and 27% have children. The online survey participants differ somewhat in composition: they are more likely to be female, they are slightly younger and they have less children. When comparing these statistics to aggregate statistics of Edinburgh job seekers, we find that we oversample women and non-whites, while the average age is very similar.

The lower part of Table 3 shows variables related to job search history, also based on the first week baseline survey. The lab participants have on average applied to 64 jobs, which lead to 0.48 interviews and 0.42 job offers.<sup>32</sup> Only 20% received at least one offer. Mean unemployment duration at the start of the study is 260 days, while the median is 80 days. About three-fourth of the participants had been unemployed for less than half a year. Participants typically receive job seekers allowance and housing allowance, while the amount of other benefits received is quite low. The online survey participants are not significantly different on most dimensions, except that they attended more job interviews.

We also compare job search behavior of participants in our study with the online survey participants. The online survey includes a question asking for the weekly number of applications sent and the weekly number of job interviews. We compare the control group lab participants to the online survey participants to assess whether participation in the study affects the participants. When using data on applications and interviews in our study, we assign both of these to the week in which search activity was performed that lead to either to these. On average this implies that applications are assigned to search activity one week before the application was send, while interviews are assigned to search activity two weeks before the interview is reported. The average number of applications are shown in panel (a) of Figure 5 and the average number of interviews in panel (b) of Figure 5. For lab participants we observe both the number of applications from job search in the lab, and the number of applications reported through other job search activities. The number of applications outside the lab is quite similar to the number reported by the online participants, while the sum of the two types

---

<sup>31</sup>Source: Office for National Statistics: NOMIS Official Labour Market Statistics. Dataset: Claimant Count conditional on unemployment duration < 12 months, average over the duration of the study. We restrict attention to durations of less than 12 months to equalize the median unemployment duration between the NOMIS query and our dataset.

<sup>32</sup>We censor the response to the survey question on the number of previous job offers at 10.

Figure 5: Jobsearch behavior online and lab participants

of applications for lab participants is somewhat higher than for the online participants. In panel (b) we find that the sum of interviews in- and outside the lab is very similar to the number reported by the online participants. The average number of weekly interviews is 0.47 for lab participants and 0.42 for online participants and these numbers are not statistically different (p-value 0.23).

## 5.2 Treatment and Control Groups

In order to evaluate the effect of the alternative interface on job search behavior and outcomes we compare treated and non-treated individuals. Both of these groups used the same interface in the first three weeks, and the alternative interface was only provided to the treatment group from week 4 onwards. This means that we can use the information from the first three weeks to correct for fixed differences between treated and control group individuals. In principal this should not be necessary though, since the treatment was assigned randomly. Still, the group fixed effects will increase precision. In Table 4 we compare characteristics of the treatment and control group to ensure that the composition of the groups is balanced.<sup>33</sup>

We compare the treated and control group on the same set of demographic and job search history variables as in Table 3, and additionally we compare job search behavior in our study over weeks 1-3. For demographic and job search history variables, only one out of 32 t-tests suggests a significant difference, which is the average number of children. In terms of job search behavior in our study over the first three weeks, we find that the control group lists on average 498 vacancies, of which 25 are viewed, and 10 are saved. Out of these, participants report to have applied to 3 and eventually get an interview in 0.09 cases. Furthermore, they report about 8 weekly applications through channels outside our study, leading to 0.03 interviews on average. For each set of vacancies (listed, viewed, saved, applied) we compute a measure of occupational broadness (see subsection 5.4), of which the average values are also shown in the table. Participants in the control group report 11 hours of weekly

<sup>33</sup>For example, it could be the case that by expressing a strong preference for a particular time slot, participants self-select into groups. Since we switch around the treatment assignment of groups in the second wave (see Table 2), this is unlikely to be problematic though.

Demographics and job search history values are based on responses in the baseline survey from the first week of the study. Search activities are mean values of search activities over the first 3 weeks of the study. <sup>a</sup> High educated is defined as a university degree. <sup>b</sup> Occupational broadness, as defined in section 5.4. <sup>c</sup> The number of hours spend on job search per week, as filled out in the weekly survey, averaged over week 2 and 3.

job search in addition to our study. In the weekly survey, participants were also asked to rate to what extent particular problems were a concern to them. On average, health problems are not mentioned as a major concern, while financial problems and strong competition in the labor market seem to be important. Finally, about 30% met with a case worker at the Jobcentre in a particular week. The values for job search behavior of the treatment group are very similar, and never differ significantly.

### 5.3 Attrition

The study ran for 12 weeks, but job seekers could obviously leave the study earlier either because they found a job or for other reasons. Thus, attrition is an inherent feature of our study, and the experimental intervention could have affected attrition rates. Differential attrition driven by differences in job finding across groups is of course of direct interest, but it also introduces challenges for the empirical analysis of search behavior, as both samples may not remain comparable over the 12 weeks.

We present attrition in panel (a) of Figure 6, for the control and treatment groups (including 95% confidence intervals).<sup>34</sup> An exit from the study is defined to occur in the week after the last session in which the individual attended a lab session, irrespective of the reason for exiting the study. We find that about 50% of the participants continue until the end of the study, and this percentage is very similar in the control and treatment group. The difference between the two curves is not significant at any duration. Of course, it is important to point out that even if we find attrition of similar magnitude in the treatment and control groups, we could still have systematic differences in unobservables over time because there may be heterogeneity in how each interface affects job seekers. We will come back to this issue in the empirical analysis.

Whenever participants dropped out, we followed up on the reasons for dropping out. In case they found a job, we asked for details, and in many cases we were able to obtain detailed information about the new job. Since job finding is a desirable outcome related to the nature of our study, we also present attrition excluding job finding in panel (b) of Figure 6. Here we present the number of participants leaving the study per week due to reasons other than finding employment. In most weeks, we lose 2 to 4 participants, and again, these numbers are very similar in control and treatment group.

The apparent lack of selection is on the one hand helpful to study how the intervention may have affected search outcomes, on the other hand, it already hints that our intervention may not have affected the rather low job finding rates in a statistically significant way. We will come back to the analysis of drop out and job finding in more detail in section (6.4.1).

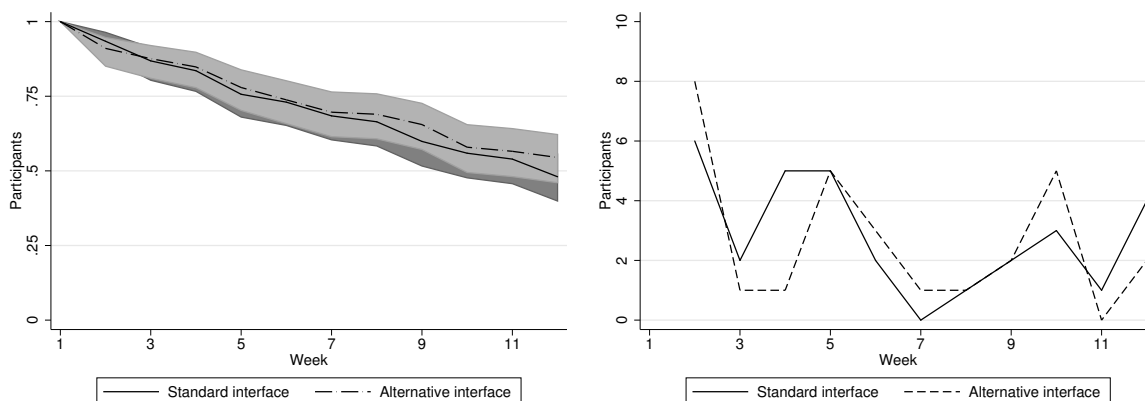

### 5.4 Measuring occupational and geographical broadness

We are interested in the effect of providing information about suitable occupations as well as geographical labor market statistics. Measuring such effects requires defining occupational and geographical broadness measures. In this subsection we provide definitions of the measures that are used in the empirical analysis. All measures are defined on the set of vacancies retrieved in a given week, independent of whether they arose due to many independent search queries or few comprehensive queries.

---

<sup>34</sup>The graph shows Kaplan-Meier estimates of the survival functions of the groups.

Figure 6: Attrition of participants in the standard and alternative interface groups

(a) Kaplan-Meier survival functions (exits include job finding), with 95% confidence intervals

(b) Attrition per week (excluding job finding)

For occupational broadness we focus on the UK Standard Occupational Classification code (SOC code) of a particular vacancy, which consists of four digits.<sup>35</sup> The structure of the SOC codes implies that the more digits two vacancy codes share, the more similar they are. Our measure of diversity within a set of vacancies is based on this principle, defining for each pair within a set the distance in terms of the codes. The distance is zero if the codes are the same, it is 1 if they only share the first 3 digits, 2 if they only share the first 2 digits, 3 if they share only the first digit and 4 if they share no digits. This distance, averaged over all possible pairs within a set, is the measure that we use in the empirical analysis.<sup>36</sup> Note that it is increasing in broadness (diversity) of a set of vacancies. We compute this measure for the set of listed and applied vacancies in each week for each participant.

For geographical broadness we use a simple measure. Since a large share of searches restricts the location to Edinburgh, we use the weekly share of a participants searches that goes beyond Edinburgh as the measure of geographical broadness.<sup>37</sup>

## 6 Empirical Analysis

We now turn to the empirical analysis. Ultimately we want to find out whether our intervention improves labor market prospects. Our data allow us to examine each step of the job search process: the listing of vacancies to which job seekers are exposed, the vacancies they apply to, the interviews they get and finally, and whether they find a job. Clearly, the ultimate outcome variable we care about is actual job finding, as well as characteristics of the job found (occupation, wage, duration, etc.), which

<sup>35</sup>The first digit of the code defines the “major group”, the second digit defines the “sub-major group”, the third digit defines the “minor group” and the fourth digit defines the “unit group” which provides a very specific definition of the occupation. Some examples are “Social science researchers” (2322), “Housekeepers and related occupations” (6231) and “Call centre agents/operators” (7211).

<sup>36</sup>Our results are robust to using the Gini-Simpson index as an alternative broadness measure.

<sup>37</sup>Note that the direct surroundings of Edinburgh contain only smaller towns. The nearest large city is Glasgow, which takes about 1-1.5 hours of commuting time.

would be important to evaluate the efficiency implications of such an intervention. Unfortunately the information we have on job finding is limited; job finding is relatively rare, and our information on job finding is rather noisy, so we should be cautious when interpreting the results. This is why we focus most of the analysis on the steps preambing job finding, specifically vacancy listings, applications and interviews. Listed vacancies are the direct result of the search criteria used by the job seeker and therefore are the most immediate measure of search behavior. Applications provide a more reliable measure of the job seekers’ interest in the vacancies.<sup>38</sup> Interviews are the next measure of interest and the next best variable to indicate interest of the employers, and since there are a lot more interviews than jobs found, it is the best indicator we have of labor market prospects. We will briefly discuss the evidence on job finding at the end of this section.

In the weekly survey that participants complete before starting to search, we ask about applications and interviews through channels other than our study. The intervention may affect these outcomes as well, since the information provided in the alternative interface could influence people’s job search strategies outside the lab. Therefore we also document the weekly applications and interviews through other channels as outcome variables. We start with presenting the econometric specification.

## 6.1 Econometric specification

Our data is a panel and our unit of observation is at the week/individual level. That is, we compute a summary statistic for each individual of her search behavior (vacancies listed, applications, interviews) in a given week. Since it is a randomized controlled experiment in which we observe individuals for three weeks before the treatment starts, the natural econometric specification is a model of difference-in-differences. To take account of the panel structure we include individual random effects. We have estimated a fixed effects model and performed a Hausman test for each of the main specifications. In none of the cases we could reject that the random effects model is consistent, such that we decide in favor of the random effects model for increased precision. Specifically, we can compare a variable measuring an outcome ( $Y$ ) in the control and treatment group before and after the week of intervention, controlling for week fixed effects ( $\alpha_t$ ), time-slot  $\times$  wave fixed effects ( $\delta_g$ ) and a set of baseline individual characteristics ( $X_i$ ) to increase the precision of the estimates. The treatment effect is captured by a dummy variable ( $T_{it}$ ), equal to 1 for the treatment group from week 4 onwards. The specification we propose is:

$$Y_{it} = \alpha_t + \delta_g + \gamma T_{it} + X_i \beta + \eta_i + \epsilon_{it} \quad (1)$$

where  $i$  relates to the individual,  $t$  to the week and  $\eta_i + \epsilon_{it}$  is an error term consisting of an individual specific component ( $\eta_i$ ) and a white noise error term ( $\epsilon_{it}$ ). Individual characteristics  $X_i$  include gender, age and age squared, unemployment duration and unemployment duration squared<sup>39</sup> and dummies indicating a short expected unemployment duration, financial concerns, being married or cohabiting, having children, being highly educated and being white.

As mentioned earlier, one important challenge with such approach has to do with attrition. If there

---

<sup>38</sup>We also constructed measures of broadness based on the viewed and saved vacancies. The results were qualitatively similar to the those obtained for the listed and applied vacancies. They are available upon request.

<sup>39</sup>Unemployment duration is defined as the reported duration at the start of the study.

Table 5: Outcome variables

	Search activity in the lab	Search activity outside the lab

Applications		
Occupational Broadness	✓	
Geographical Broadness	✓	
Number	✓	✓
Interviews		
Number	✓	✓
Core and non-core occupations	✓	

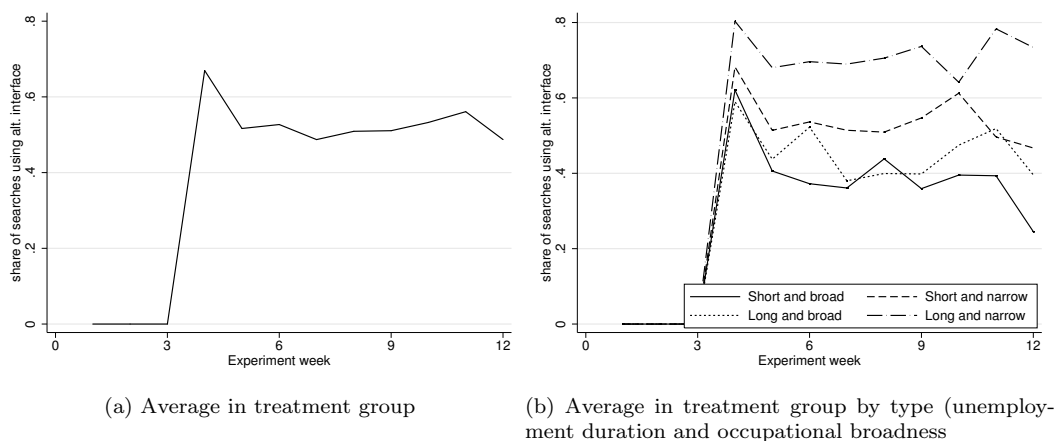

is differential attrition between treatment and control groups, it could be that both groups differ in unobservables following the treatment. Differential attrition is of course particularly plausible because our treatment could have affected job finding and therefore study drop out. We proceed in two ways to address this potential concern. First, we documented in Section 5.3 attrition across treatment and control groups and found no evidence of asymmetric attrition. Second, our panel structure allows us to control for time-invariant heterogeneity and use within-individual variation. When we estimate a random and fixed effects model, the Hausman test fails to reject the latter. Since the treatment itself is assigned at the group-level it is unlikely to be correlated with unobserved individual characteristics. However, differential attrition could create correlation between unobservable individual characteristics and would therefore lead to rejection of the random-effects model. The fact that we can never reject this model is thus an indication that there is no (strong) differential attrition between treatment and control groups.

We summarize in Table 5 the outcome variables of interest. For listed vacancies and applications we look at broadness (occupational and geographical) and the number. For interviews we only look at the number, since the number is too small to compute informative broadness measures. As an alternative, we asked individuals at the beginning of the study about three “core” occupations in which they are looking for jobs, and we can estimate separate treatment effects for interviews in core and non-core occupations. For the number of applications and interviews we also look at activity outside the lab. Note that applications and interviews through activity in lab are assigned to the week in which the search activity was performed. A similar correction is made for applications and interviews through other channels, which is described in more detail in the relevant sections.

Another important aspect relevant for the econometric specification is the potential heterogeneity of effects across individuals. Given the nature of the intervention, it is likely that the treatment affects different individuals differentially. In order for our intervention to affect job prospects, it has to open new search opportunities to participants and participants have to be willing to pursue those opportunities. Participants may differ in terms of their search strategies. We expect our intervention to broaden the search for those participants who otherwise search narrowly, which we will measure by their search in the weeks prior to the intervention. For those who are already searching broadly

Figure 7: Share of searches that uses alternative interface

in the absence of our intervention it is not clear whether we increase the breadth of their search. We therefore estimate heterogeneous treatment effects by initial broadness.<sup>40</sup>

Second, the willingness to pursue new options depends on the incentives for job search, which change with unemployment duration for a variety of reasons. Longer-term unemployed might be those for whom the search for their preferred jobs turned out to be unsuccessful and who need to pursue new avenues, while they are also exposed to institutional incentives to broaden their search (the Jobcentres require job seekers to become broader after three months). Note again that we are always comparing otherwise identical individuals in the treatment and control groups, so the incentives to broaden their search by themselves would not be different, but the information we provide to achieve this differs. We therefore also interact the treatment effect with unemployment duration. In the subsequent section we provide a simple theoretical model formalizing the channels that may explain differential effects.

Note that since we did not force job seekers to use the alternative interface, our intervention is an intention-to-treat. Panel (a) of Figure 7 plots the fraction of users of the alternative interface over the 12 weeks. On average we find that around 50% of the treated participants use the alternative interface over the 8 weeks and this fraction remains quite stable throughout. This does not mean that only 50% of the treatment group is treated though because all participants in the treatment group used the alternative interface at least once and were therefore exposed to recommendations and suggestions based on their profile. It could be that they used this information while reverting back to searching with the standard interface.

Bearing this in mind, we now document the effects of the intervention on the various steps of the search process. We will present the results on the treatment effect only ( $\gamma$ ) as well as the interaction effects between the treatment and the subgroups of interest, for the sake of brevity. For the amount of search activity we report the full results including all other covariates in Table 18 in the Appendix.

<sup>40</sup>We split the sample at the median level of broadness over the first three weeks.

Table 6: Effect of intervention on listed vacancies

	Broadness of listings		Number of listings
	(1) Occupational	(2) Geographical	(3) Lab
Treatment	0.11*** (0.04)	-0.01 (0.02)	-0.68 (30.98)
Treatment			
X occupationally broad	-0.16*** (0.05)	0.03 (0.02)	-35.10 (38.01)
X occupationally narrow	0.38*** (0.05)	-0.05** (0.02)	33.79 (37.09)
Model	Linear	Linear	Linear
Observation weeks	1-12	1-12	1-12
$N$	2392	2399	2401

Each column represents two separate regressions. All regressions include group fixed effects, week fixed effects, individual random effects and individual characteristics. Standard errors in parentheses. \*  $p < 0.10$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$

## 6.2 Effects on Listed vacancies

The most immediate measure of search relates to listed vacancies, i.e., the listing of vacancies that appears on the participants' screen as a return to their search query. By default the list is ordered by date of vacancy posting (most recent first), but participants can choose to sort them according to other criteria such as job title, location and salary. Note that we limit ourselves to the list of vacancies the participants actually saw on their screen. A page on the screen is limited to at most 25 listed vacancies, and participants have to actively move from one screen to the next to see additional vacancies. Thus, we exclude the vacancies on pages that were not consulted by the participant. As mentioned earlier, all analysis are at the weekly level and, thus, we group all listings in a week together.<sup>41</sup>

We have two variables measuring how broad participants search, one in terms of occupation (as described in section 5.4), the other in terms of geography (fraction of vacancies outside Edinburgh metropolitan area). In this section both are based on the set of listed vacancies of an individual. We also measure the number of vacancies that were listed.

We estimate a simple linear model with individual random effects (equation (1)). The results are presented in Table 6. The first row presents a highly significant positive overall effect on broadness of search in terms of occupation. The broadness measure increases with 0.11, which amounts to

<sup>41</sup>The alternative interface tends to necessitate less search queries than the standard interface to generate the same number of vacancies because on the alternative interface one query is intended to return all vacancy even for other related occupations. For that reason the weekly analysis seems more interesting compared to results at the level of an individual query, for which results arise rather mechanically.

approximately one-fifth of a standard deviation. The alternative interface altered job seekers’ search such that they are exposed to a broader set of occupations. We find no evidence of an overall effect on geographical broadness or on the number of listed vacancies. In rows two and three we split the sample according to how occupationally broad job seekers searched in the first three weeks.<sup>42</sup> We find clear heterogeneous effects: those who looked at a more narrow set of occupations in the first three weeks become broader, while those who were broad become more narrow as a result of the intervention. Note that these effects are not driven by a regression to the mean since we compare narrow/broad searchers in our treatment group to similarly narrow/broad searchers in our control group. We also find evidence of a substitution effect in terms of geographical broadness. Those who expand their search in terms of occupation appear to also become more narrow in the geographical area they look at, possibly because they now find more jobs within close proximity and have a lower need to search further away. The opposite is true for those who narrow their search in terms of occupation.<sup>43,44</sup>

The different effects can be reconciled in a setting where broad searchers find many occupations plausible and use the additional information to narrow down the suitable set, while narrow searchers find few occupations suitable and use the additional information to broaden this set. This mechanism is more formally described in Section 7.

Finally, we split the effect further depending on how long job seekers have been searching for a job and present the results in Table 7. We interact the intervention effect with two groups: short term unemployed (with unemployment duration of less than the median of 80 days) and long term unemployed (with unemployment duration above the median). The effect is estimated for four groups: interactions of occupational broadness and unemployment duration. We find that results do not change much, though standard errors are larger. We still find that occupationally narrow searchers become broader while those that were already broad become more narrow, irrespective of unemployment duration.

### 6.3 Effects on Applications

The second measure of search behavior relates to applications. Here we have information about applications based on search activity conducted inside the laboratory as well as outside the laboratory which we collected through the weekly surveys.

---

<sup>42</sup>There are, of course, several other dimensions along which we could estimate heterogeneous effects. Since we have only a limited sample size, we decided to estimate only heterogeneous effects by initial broadness. For this factor we have a clear hypothesis for the effect of the intervention, while estimation of heterogeneous effect along many other dimension might be considered data mining. Note however that initial broadness is correlated with other factors and may therefore pick up the difference in effect along other dimensions. In particular, being an initially broad searcher is correlated with age (correlation coefficient is -0.36), gender (0.07), being in a couple (-0.06), having children (-0.19) and being higher educated (-0.11).

<sup>43</sup>In the appendix we also report estimates when we split the sample according to broadness along the geographical dimension at the median (see Table 15). The results are similar (those who were searching broadly become more narrow and vice versa, and there is some trade-off with occupational broadness). This could still be driven by initial occupational broadness, since this is negatively correlated with initial geographical broadness (coefficient -0.36) and is not controlled for. Indeed, when we split both by occupational and geographical broadness the effects are driven by the occupational dimension, which we will henceforth focus on.

<sup>44</sup>The difference in the number of observations between the columns in Table 6 and similar tables that follow is due to the fact that we can only compute the occupational (geographical) broadness measure if the number of listed is two (one) or larger, which excludes different numbers of observations depending on the variable of interest.

Table 7: Effect of intervention on listed vacancies - interactions

	Broadness of listings		Number of listings
	(1)	(2)	(3)
	Occupational	Geographical	Lab
Treatment			
X long unempl. and occ. broad	-0.18*** (0.06)	0.08*** (0.03)	52.21 (48.52)
X short unempl. and occ. broad	-0.14** (0.06)	-0.02 (0.03)	-124.71** (49.10)
X long unempl. and occ. narrow	0.38*** (0.06)	-0.03 (0.02)	78.30* (47.40)
X short unempl. and occ. narrow	0.38*** (0.06)	-0.07*** (0.02)	-11.07 (47.16)
Model	Linear	Linear	Linear
Observation weeks	1-12	1-12	1-12
<i>N</i>	2392	2399	2401

Each column represents one regression. All regressions include group fixed effects, week fixed effects, individual random effects and individual characteristics. Standard errors in parentheses. \*  $p < 0.10$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$

Table 8: Effect of intervention on applications

	Broadness of applications		Number of applications		
	(1)	(2)	(3)	(4)	(5)
	Occupational	Geographical	Lab	Outside lab	Total
Treatment	-0.00 (0.13)	-0.06** (0.03)	0.10 (0.11)	-0.06 (0.06)	-0.02 (0.06)
Treatment					
X occupationally broad	-0.19 (0.16)	-0.04 (0.03)	-0.10 (0.11)	-0.11 (0.08)	-0.12 (0.07)
X occupationally narrow	0.14 (0.16)	-0.09*** (0.03)	0.31** (0.16)	-0.01 (0.08)	0.06 (0.08)
Model	Linear	Linear	Neg. binomial	Neg. binomial	Neg. binomial
Observation weeks	1-11	1-11	1-11	1-11	1-11
$N$	939	1177	2251	2016	1984

Each column represents two separate regressions. All regressions include group fixed effects, week fixed effects, individual random effects and individual characteristics. Columns (3)-(5) are negative binomial model regressions where we report  $[\exp(\text{coefficient}) - 1]$ , which is the percentage effect. Standard errors in parentheses. \*  $p < 0.10$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$

For the applications based on search in the laboratory, we asked participants to indicate for each vacancy saved in the previous week whether they actually applied to it or not.<sup>45</sup> We can therefore precisely map applications to the timing of the search activity. This is important as there may be a delay between the search and the actual application; so applications that are made in week 4 and after could relate to search activity that took place before the actual intervention. For the applications conducted based on search outside the laboratory, we do not have such precise information. We asked how many applications job seekers made in the previous week but we do not know the timing of the search activity these relate to. For consistency, we assume that the lag between applications and search activity is the same inside and outside the laboratory (which is one week) and assign applications to search activity one week earlier. As a result, we have to drop observations based on search activity in the last week of the experiment, as we do not know observe applications related to this week.

Since the distribution of applications contains a large share of zeros, we estimate a negative binomial model, with individual random effects. For these models we report  $[\exp(\text{coefficient}) - 1]$ , which is the percentage effect.

The results are presented in Table 8. We find no overall treatment effect on applications, except for a decrease in their geographical broadness (approximately one-fifth of a standard deviation). When we split the sample according to initial occupational broadness, we find that those who searched more narrowly in terms of occupation apply to more vacancies when searching with the alternative interface. The number of applications increases by 31%. This increase in applications based on search activity in the lab has no negative spillovers on applications based on search done outside the lab. We find no significant effect on the broadness measure in terms of occupations, but there is a negative effect on geographical broadness for the occupationally narrow job seekers.<sup>46</sup>

Again, we split these effects by the duration of unemployment and report results in Table 9. We find that occupational broadness goes down for long term unemployed broad searchers, while it goes up for short term unemployed narrow searchers (though both are not significant as a result of larger standard errors). We find that the increase in applications in the lab is concentrated among the long-term unemployed, and in particular those that initially searched narrow occupationally. Furthermore we find that long term unemployed occupationally broad searchers reduce their applications somewhat.

## 6.4 Effects on interviews

We now turn to interviews, the variable that is most closely related to job prospects. Since the number of interviews per week is always very small, we cannot calculate broadness measures. So we only look at a measure of the number of interviews obtained as a result of search conducted inside the laboratory and outside the laboratory.<sup>47</sup> Because of the large share of zeros, we estimate a Poisson model with

---

<sup>45</sup>If they have not applied, they are asked whether they intend to apply and will then be asked again whether they did apply or not.

<sup>46</sup>When splitting the sample according to how narrowly people searched in terms of geography, we find no evidence of heterogeneous effects. Results are presented in the appendix in Table 16.

<sup>47</sup>For interviews reported outside the lab we restrict observations to 0,1,2 or 3 and more, because of some outliers. Results are similar when no such restriction is imposed.

Table 9: Effect of intervention on applications - interactions

	Broadness of applications		Number of applications		
	(1)	(2)	(3)	(4)	(5)
	Occupational	Geographical	Lab	Outside lab	Total
Treatment

Each column represents one regression. All regressions include group fixed effects, week fixed effects, individual random effects and individual characteristics. Columns (3)-(5) are negative binomial model regressions where we report  $[\exp(\text{coefficient}) - 1]$ , which is the percentage effect. Standard errors in parentheses. \*  $p < 0.10$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$

Table 10: Effect of intervention on interviews

	Number of interviews		
	(1) Lab	(2) Survey	(3) Total
Treatment	0.56 (0.47)	0.25 (0.21)	0.29* (0.19)
Treatment			
X occupationally broad	-0.44 (0.26)	0.06 (0.23)	-0.03 (0.19)
X occupationally narrow	1.35** (0.79)	0.39* (0.26)	0.52** (0.25)
Model	Poisson	Poisson	Poisson
Observation weeks	1-10	1-10	1-10
$N$	2098	1776	1744

Each column represents two separate regressions. All regressions include group fixed effects, week fixed effects, individual random effects and individual characteristics. Columns (1)-(3) are Poisson regression models where we report  $[\exp(\text{coefficient}) - 1]$ , which is the percentage effect. Standard errors in parentheses. \*  $p < 0.10$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$

individual random effects.<sup>48</sup> Again we report  $[\exp(\text{coefficient}) - 1]$ , which is the percentage effect. As was done for applications, we assign interviews to the week in which the search activity was performed, and assign interviews through channels other than the lab to search activity two weeks earlier. As a results we exclude weeks 11 and 12 of the experiment, because for job search done in these weeks we do not observe interviews.

Results are presented in Table 10. There is a positive effect of the treatment on the total number of interviews, which is significant at the 10% level. We also find positive effects on interviews on the two separate dimensions of search in the lab and search outside the lab, though neither is statistically significant by itself. When splitting the sample according to broadness of search, we find that the effect is entirely driven by those who searched narrowly in terms of occupation. For this group the number of interviews increases for search activity conducted both in the lab and outside. This seems to indicate that the additional information is not only helpful for search on our platform, but also guides behavior outside. Note that this is also the group for which the number of applications increased.<sup>49</sup>

<sup>48</sup>Due to the relatively small number of interviews observed, we cannot estimate a negative binomial model and use a Poisson regression model instead.

<sup>49</sup>We find little evidence of heterogeneity in treatment effects when we split the sample according to initial geographical broadness. We find a significant treatment effect for those who searched broadly geographically, but all the coefficients are positive across the board and not significantly different across sub-groups. Results are presented in the appendix in Table 17.

Table 11: Effect of intervention on interviews - interactions

	Number of interviews		
	(1) Lab	(2) Survey	(3) Total
Treatment			
X long unempl. and occ. broad	-0.14 (0.56)	-0.28 (0.20)	-0.27 (0.19)

Each column represents three separate regressions. All regressions include group fixed effects, week fixed effects, individual random effects and individual characteristics. Columns (1)-(2) are Poisson model regressions where we report  $[\exp(\text{coefficient}) - 1]$ , which is the percentage effect. Standard errors in parentheses.  
 \*  $p < 0.10$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$

When we further split the sample according to length of unemployment duration, we find that the positive treatment effects on the narrow searchers is mainly driven by the long term unemployed. This group gets a significant increase in the number of interviews both as a result of search activity done inside the lab and outside the lab. These findings highlight that our intervention is particularly beneficial to people who otherwise search narrowly and who have been unemployed for some months. Overall, it does not seem detrimental to those that became more narrow in their search.

Even though the set of weekly interviews is too small to compute broadness measures, we did ask individuals at the beginning of the study to indicate three core occupations in which they search for jobs, and observe whether an interview was for a job in someone’s core occupation or for a job in a different occupation. We had seen earlier that the alternative interface was successful in increasing the occupational broadness of listed vacancies, and separate treatment effects on interviews in core vs non-core occupations allow some assessment whether this lead to more “broadness” in job interviews. Results are presented in Table 12. We indeed find that the increase in the number of interviews relative to the control group comes from an increase in non-core occupations that were not their main search target at the beginning of our study. As the number of interviews becomes small when splitting between core and non-core, we cannot split the sample further by subgroups.

Our findings suggest that the alternative interface may be more beneficial to those that search narrowly and have been relatively long unemployed. This finding is supported by statistics on usage of the interface over time. Panel (b) of Figure 7 shows the evolution of the fraction of treated participants using the interface, splitting the sample by occupational broadness and unemployment duration. We find that long term narrow searchers are indeed using the interface more than the other groups (with around 70% of them using the interface in contrast to around 45% for the other groups), and this difference is statistically significant. The fractions remain quite stable over the 8 weeks. This finding

Table 13: Summary statistics on job finding and drop out for weeks 3 and 12

	In Study - No Job	Found a Job	Out of Study	Job finding week	
				mean	(std)
<i>Week 3</i>					
Standard interface	86.1%	8.0%	6.0%	2.2	(0.6)
Alternative interface	88.3%	6.9%	4.8%	2.1	(0.7)
<i>Week 12</i>					
Standard interface	56.7%	28.4%	15.0%	7.6	(2.2)
Alternative interface	63.7%	21.8%	14.5%	8.1	(2.6)

supports the intuition that some groups of job seekers benefit more from the intervention and are therefore more willing to use the alternative interface. This group, the long-term unemployed narrow searchers is exactly the group for which we find the most pronounced positive effects.

One way to rationalize the findings is that those who search narrowly are content to do so in the early periods of unemployment where they think that their chances of finding a job within their narrow focus is sufficiently high. Additional information does not alter their view that these occupations are the most relevant ones, and does not change their search very much. This is the group of short-term narrow searchers. For some of them it turns out that they cannot find a job within their narrow focus and they become less convinced of their chances in these occupations. They might still not know which other occupations might be suitable to them, and continue to be narrow. These are the longer-term narrow searchers. Giving them additional information has positive effects, as they would like to pursue new options but do not yet know where. Finally, some people search broadly, either right away because they do not have any clearly preferred occupations (or because these occupations are too small) or because over time they got disappointed by their initial focus and become broader. For these people, getting information singles out some occupations relative to others, and rather than searching everywhere they save on search effort and become more narrow. We formalize this below.

#### 6.4.1 Effects on Job finding

We now return to the analysis of job finding. As mentioned earlier, we should be cautious when interpreting the results because a) the sample is small, b) attrition from one week to the next for unexplained reasons is unfortunately of the same order of magnitude as the confirmed job finding rate and c) once participants found a job, they had little incentive to inform us about the details.<sup>50</sup>

We classify job seekers in three categories depending on the information recorded in week 3 (before the intervention) and week 12 (last week of the intervention): Job seekers are either (1) present in the study and having no job (“no job”), (2) not present in the study and unclear outcome (“out of study”), (3) not present in the study and having found a job (“job”).

Table 13 presents the distribution of job seekers across categories, as well as the average length (in weeks) job finders had to wait to find a job. Note that we record the week they accepted a job offer, not the week the job actually started. For week 12, we report the distribution for those who were

<sup>50</sup>We tried to follow-up by calling them at least 3 times, though for a non-trivial share of the attrition we still do not observe perfectly whether the person found a job or just quit the study.

Table 14: Treatment effects on job finding rate

	(1)	(2)
Treatment	-0.23 (0.25)	-0.15 (0.46)
Occupationally broad		0.77* (.38)
Treatment x Occupationally broad		-0.13 (0.55)
<i>N</i>	256	256

Proportional Cox Hazard model, with session group dummies, and controls for gender, age, age squared, ethnicity (white), cohabiting, university degree, number of children and financial concerns. We exclude observations censored at 3 weeks or less. Reported values are coefficients. \*  $p < 0.10$ .

still in the study in week 4 and have therefore been exposed to the new interface if they were in the treatment group.

Since we have around 15% of our sample who dropped out and we do not know if they found a job or not, it is difficult to draw conclusions based on these numbers. There is indication that the job finding rate is slightly higher in the standard interface than in the alternative interface already in week 3, however this appears more pronounced in week 12, which deserves further attention.

We estimate a simple duration model where the duration is the number of weeks we observe an individual until she/he finds a job. Since we know when each individual became unemployed, we can calculate the total unemployment duration and use this as a dependent variable. This variable is censored for individuals who drop out of the study or who fail to find a job before the end of the study. We estimate a proportional Cox hazard model with the treatment dummy as independent variable, controlling for additional individual characteristics and group session dummies.

We report estimates for the entire sample and for the sub-samples conditioning on initial search type (narrow vs broad search). The results are presented in Table 14. We fail to find significant differences in the hazard rates across treatments. That is, we have no evidence that the job seekers exposed to the alternative interface were more or less likely to find a job (conditionally on still being present in week 4). Of course, these results are only suggestive given the small numbers.

## 7 An Illustrative Model

In the empirical section we saw that our information intervention increases the occupational broadness and the number of applications mainly for long-term but narrow searchers, and increases their job interviews. Searchers that already search broadly without our intervention decrease their broadness,

with insignificant effects on interviews. Here we briefly sketch a very stylized occupational job search model that is capable of rationalizing these findings and of organizing our thoughts about the driving forces. The goal is not to provide the richest framework, but to provide a simple setup in which the previous findings can be captured with intuitive arguments in a coherent framework.

A job seeker can search for jobs in different occupations, indexed  $i \in \{1, \dots, I\}$ . For each occupation she decides on the level of search effort  $e_i$ . Returns to searching in occupation  $i$  are given by an increasing but concave function  $f(e_i)$ .<sup>51</sup> The returns to getting a job are given by wage  $w$  and are the same across occupation, and  $b$  denotes unemployment benefits. The cost of search is given by an increasing and convex function  $c(\sum e_i)$ .<sup>52</sup>

The individual is not sure of her job prospects within the various occupations. If her job prospects are good she obtains a job in occupation  $i$  with arrival probability  $a_H f(e_i)$ , otherwise she obtains a job with probability  $a_L f(e_i)$ , where  $a_H > a_L$ . The uncertainty can be about whether the skills of the job seeker (still) meet the requirements of the occupation. The individual knows that there is an objective probability  $q_i$  that someone with her background has good job prospects in occupation  $i$ . She does not know this probability, but only knows its distribution  $Q_i$  with support  $[q_i, \bar{q}_i]$ . Without further information her belief of having good job prospects is simply the mean  $p_i = \int q_i dQ_i$ .

Given this average prior and her effort, her expected chances of getting a job offer in occupation  $i$  are

$$h(p_i, e_i) = f(e_i)(p_i a_H + (1 - p_i) a_L).$$

Given a vector of beliefs  $p = (p_1, \dots, p_I)$  and a vector of search effort in the various occupations  $e = (e_1, \dots, e_I)$ , the overall expected probability of being hired in some occupation is

$$H(p, e) = 1 - \prod_i (1 - h(p_i, e_i))$$

where the product gives the probability of not getting a job offer in any occupation.

Assume the unemployed job seeker lives for  $T$  periods, discounts the future with factor  $\delta$ , and if she finds a job this is permanent. Obviously searching in an occupation changes the beliefs about it. An individual who has a prior  $p_i^t$  at the beginning of period  $t$  and spends effort  $e_i^t$  during the period but does not get a job will update her beliefs about the chance of being a high type in occupation  $i$  by Bayes rule. Let  $B(p_i^t, e_i^t)$  denote this new belief. For interior beliefs we have<sup>53</sup>

$$p_i^{t+1} = B(p_i^t, e_i^t) = \begin{cases} = p_i^t & \text{if } e_i^t = 0 \\ < p_i^t & \text{if } e_i^t > 0, \end{cases} \quad (2)$$

<sup>51</sup>The decreasing returns capture that the number of job opportunities within an occupation may be limited. We are focusing on the individual worker's search here, and do not additionally model the aggregate matching function that might depend on the total number of vacancies and the number of other job seekers who explore the same occupation. All of this is suppressed as the individual takes it as given. For simplicity we also abstract from heterogeneity in occupations which might make the return to search occupation-specific.

<sup>52</sup>In models with only one occupation it is immaterial whether  $c$  is convex or  $f$  concave or both. With multiple occupations, we chose a setup where the costs are based on total effort, which links the various occupations, while the return to search is occupation specific. In this setting, if returns were linear all search would be concentrated in only one market. If costs were linear, then changes in one market would not affect how much individuals search in other markets. So both play a separate role here.

<sup>53</sup>The exact formula in this case is  $B(p_i^t, e_i^t) = p_i^t [1 - f(e_i^t) a_H] / [1 - p_i^t f(e_i^t) a_H - (1 - p_i^t) f(e_i^t) a_L]$ . Note also that beliefs do go up if the person finds a job, but under the assumption that the job is permanent this does no longer matter.

since there is no learning without effort, and the individual becomes more pessimistic if she does put effort but does not get a job. Let  $B(p, e) = (B(p_1, e_1), \dots, B(p_I, e_I))$  denote the vector of updates.

The state variable for an individual is the time period  $t$  because of her finite life-time, and her belief vector at the beginning of this period  $p$  ( $= p^t$ ). Given this, she chooses her search effort vector  $e$  ( $= e^t$ ) to maximize her return. She obtains for sure her outside option of doing nothing in the current period: her current unemployment benefit payment and the discounted value of future search. Additionally, if she finds a job, she gets the lifetime value of wages ( $W_t$ ) to the extent that they exceed her outside option. Finally, she has to pay the search effort costs. So the return to search is given by

$$R_t(p) = \max_e \left( b + \delta R_{t+1}(B(p, e)) + H(p, e) \left( W_t - (b + \delta R_{t+1}(B(p, e))) \right) - c \left( \sum_i e_i \right) \right) \quad (3)$$

The model implies that an individual may search in multiple occupations due to decreasing returns in each one. The distribution of her effort across occupations depends on the set of priors  $p_i$ ,  $i \in 1, \dots, I$ . For our purposes a two-period model suffices (for which  $R_3 = 0$ ,  $W_2 = w$  and  $W_1 = w(1 + \delta)$ ).<sup>54</sup> The first period captures the newly unemployed, and the second period the longer-term unemployed.

The unanticipated introduction of the alternative interface provides an additional source of information on occupations. It displays a list of occupations suitable for someone with her background. In general, this implies that for these occupations the individual may update her beliefs positively, while for those not on the list she may update her beliefs downwards. To formalize this mechanism, assume that an occupation is only featured on the list if the objective probability  $q_i$  of having good job prospects exceeds a threshold  $\hat{q}$ . In the first period of unemployment this means that for any occupation on the list the individual updates her belief upward to the average of  $q_i$  conditional on being larger than  $\hat{q}$  (i.e.,  $p_i^1 = \int_{\hat{q}}^{\bar{q}_i} q_i dQ_i / \int dQ_i$ ). For occupations that are not on the list her beliefs decline to the average of  $q_i$  conditional of  $q_i$  being below  $\hat{q}$  (i.e.,  $p_i^1 = \int_{q_i}^{\hat{q}} q_i dQ_i / \int dQ_i$ ). Obviously these updates also apply if the alternative interface is introduced at a later period of unemployment as long as the individual has not yet actively searched in this occupation. If the individual has already exerted search effort the updating is more complicated but obviously being on the list continues to be a positive signal.<sup>55</sup> The alternative interface induces an update in belief  $p_t$  in the period that it is introduced, but given this update maximization problem (3) continues to characterize optimal behavior.

In order to gain some insights in how this affects the occupational broadness of search, consider for illustration two types of occupations. Occupations  $i \in 1, \dots, I_1$  are the “core” ones where the job seeker is more confident and holds first period prior  $Q_i = Q_H$  leading to average belief  $p_i = p_h$ , while she is less confident about the remaining “non-core” occupations to which she assigns prior  $Q_j = Q_L$  with average  $p_j = p_L$  such that  $p_L \leq p_H$ . Assume further that core occupations enter the list in the alternative interface for sure (i.e.,  $q_H > \hat{q}$ ), which means that the alternative interface provides no information content for them. For non-core occupations we assume that there is information content

<sup>54</sup>Infinitely lived agents would correspond to a specification with  $W_t = w/(1 - \delta)$  and  $R_t(p) = R(p)$ .

<sup>55</sup>Consider a period  $t$  with prior  $p_i^t$ . The information that occupation  $i$  is on the list in the alternative interface can be viewed as changing the very first prior  $p_i^1$ , and this translates into the updated prior in period  $t$  by successively applying the updating formula (2), using the efforts that have been exerted in the interim.

Figure 8: Model Illustration: narrow search

(a) Narrow search, short-term unemployed: High belief ( $p_H$ ) in first three occupations relative to other occupations ( $p_L$ ). Small changes in beliefs (arrows) do not move beliefs above the threshold  $\bar{p}$  to be included into the search.

(b) Narrow search, longer-term unemployed: Update in first three occupations leads to lower belief in these (dashed arrows for  $p_H$  in first three occupations). This brings threshold  $\bar{p}$  closer to the beliefs in other occupations ( $p_L$ ), so that some additional information moves some occupations above the threshold and broadens search (arrows for occupations 4-10).

in the alternative interface, but not too much.<sup>56</sup> For ease of notation, denote by  $e_H$  the search effort in the first period in core occupations, and by  $e_L$  the same for non-core occupations.

The following results are immediately implied by problem (3): given the search period, the number of core occupations and the current belief about them, there exists a level  $\bar{p}$  such that the individual puts zero search effort on the non-primary occupations iff  $p_i^t \leq \bar{p}$  for each non-core occupation  $i$ . This is obvious in the limit when the beliefs about the non-core occupations tend to zero. The level of  $\bar{p}$  is increasing in the belief about the core occupations (if core occupations are more attractive search is expanded there, which drives up the marginal cost of any further search in non-core occupations) and in the number of core occupations (again core occupations as a whole attract more search effort).

We depict our notion of an individual who is recently unemployed and narrow in Figure 8 (a). The person is narrow because her beliefs in her core occupations ( $p_H$ ) are high enough that she does not want to search in the secondary occupations ( $\bar{p} > p_L$ ). This individual concentrates so much effort onto the primary occupations that marginal effort costs are large, and therefore she does not want to explore the less likely occupations. In fact, the distance in employment prospects is so large that small changes in the prior  $p_L$  induced by the alternative interface - indicated by the thick arrows in the figure - do not move them above the threshold  $\bar{p}$ . So there would be no difference in search behavior with or without the alternative interface.

In part (b) we depict our notion of the same individual after a period of unemployment. Her prior at the beginning of the second period is derived by updating from the previous one. After unsuccessful search in the core occupations it has fallen there, as indicated by the lower priors for the first three occupations. Since she did not search in non-core occupations, her prior about them remains

<sup>56</sup>Information content means that  $\hat{q} \in (\underline{q}_L, \bar{q}_L)$ . There is not too much information content if  $\bar{q}_L - \underline{q}_L < \epsilon$  for sufficiently small  $\epsilon$ , so that the difference between occupations on the list and those off the list is bounded by  $\epsilon$ .

Figure 9: Model Illustration: broad search

(a) Broad search, short-term unemployed: Beliefs are rather similar and all beliefs are above the search cutoff  $\bar{p}$ . Small changes in beliefs (arrows) can move some occupations below this cutoff, making the person narrower.

(b) Broad search, longer-term unemployed: Similar to part (a) but at a lower level of beliefs.

unchanged. This individual is still narrow if  $p_L$  remains below the new  $\bar{p}$ , but now these two are closer together.<sup>57</sup> Now information that changes the beliefs moves some of the non-core occupations above the threshold  $\bar{p}$ , which makes it attractive to search there and the individual becomes broader. This necessarily requires more search effort in total. This raises the search costs, which the individual is only willing to do if job prospects increase. So this rationalizes why longer-unemployed individuals become broader and apply more and see interviews increase, while at low unemployment durations there is little effect.

Figures 9 (a) and (b) depict individuals who are already broad in the absence of an information intervention, since the threshold  $\bar{p} < p_L$ . This could be because an individual has rather equal priors already early in unemployment, as shown in panel (a). Alternatively it could be a person whose beliefs fell over the course of the unemployment spell to a more even level, as shown in (b) (possibly from an initially uneven profile such as in Figure 8 (a)). In both cases, the person already searches in all occupations, but additional negative information (i.e., occupations that are not included in the list that is recommended in the alternative interface) might move the prior of those occupations so low that the person stops searching there and becomes narrow. Effects on search effort and job prospects are ambiguous: search effort can now be concentrated more effectively on promising occupations which raises effort and job prospects; alternatively the negative information on some occupations can translate simply into reduced search effort which is privately beneficial but reduces job prospects. Depending on parameters, either can dominate. This can rationalize why otherwise broad searchers become narrower in our treatment group, without significant effects on job prospects.

Thus, the model is able to replicate differential effects by broadness and unemployment duration. In this model, as in all models of classical decision theory, more information can only improve the expected

<sup>57</sup>Note that other factors such as regulations on job search activities imposed by the Jobcentre may also affect broadness of search. Though the mechanism would be different, the resulting effect on the distribution of search effort across occupations would be similar.

utility for the individual. This is true even for reduced search by otherwise broad individuals. But socially, when taking into account unemployment benefit payments, it can lead to costs if some of the broad searchers have parameters that lead them to cut back on search effort in non-core occupations in a way such that their job prospects decline. It makes clear that targeting our intervention might be appropriate to prevent such outcomes. More studies might be necessary to confirm both the empirical findings and our rationalization here.

## 8 Conclusion

We provided an information intervention in the labor market by redesigning the search interface for unemployed job seekers. Compared to a “standard” interface where job seekers themselves have to specify the occupations or keywords they want to look for, the “alternative” interface provides suggestions for occupations based on where other people find jobs and which occupations require similar skills. It provides this information in an easily accessible way by showing two lists, and provides all associated vacancies at the click of a button. While the initial costs of setting up such recommendations might be non-trivial, the intervention shares the concept of a “nudge” in the sense that the marginal cost of providing the intervention to more individuals is essentially costless and individuals are free to opt out and continue with the standard interface.<sup>58</sup> A major aim of the intervention was to keep things simple for participants, so little cognitive effort is required to learn on the alternative interface.

We find that the alternative interface significantly increases the overall occupational broadness of job search. In particular, it makes initially narrow searchers consider a broader set of options and apply more, but decreases occupational broadness for initially broad searchers, even though overall the former effect dominates. Overall we find a positive effect on job interviews. This effect is driven by participants with longer-than-median unemployment duration in our study. This can be rationalized if those who just got unemployed concentrate their efforts on those occupations they have most hopes in and are not interested in investing time into new suggestions. If this does not lead to success, they become more open to new ideas, but might remain narrow for longer in the absence of new information.

Our findings indicate that targeted job search assistance can be effective, in a cost-efficient way. Yet it should be obvious that additional larger-scale roll-out of such assistance would be required to document the full effects. The sample size in this study is restrictive, so is the absence of access to administrative data to follow individuals longer-term. This prohibits conclusive findings on unemployment duration or the length and compensation of jobs they might find. The study also does not allow the assessment of general equilibrium effects that arise if all unemployed obtain more information.

Nevertheless, the paper documents the positive effects that can be obtained by targeted interventions on information. As a first study on job search design on the web, it offers a new route how to improve market outcomes in decentralized environments and hopefully opens the door to more investigations in this area.

---

<sup>58</sup>It is essentially costless to provide our information to a larger set of existing participants on a job search site such as Universal Jobmatch. The acquisition of new participants is by no means costless and prevents us to roll this out in a larger scale ourselves. See also Footnote 24.

## 9 Appendix

### 9.1 Extended results

In Table 15 we present the effect of the intervention on listed vacancies, separated by initial geographical broadness. An individual is defined to be geographically broad if his share of searches that is outside the Edinburgh area is above the median in the first 3 weeks of the study. The overall effect is presented in the first row (the same as in Table 6), which shows that the intervention increased occupational broadness. When splitting the effect by initial geographical broadness (rows (2) and (3)), we find that the positive effect is only prevalent among those that are geographically broad. However, when we estimate four effects for the combinations of initial occupational and geographical broadness (rows (4)-(7)), we find that occupational broadness is the main determinant of the effect. Irrespective of geographical broadness, those that were occupationally narrow become broader, while those that were occupationally broad become narrower. In column (2) we find a similar pattern for the effect on geographical broadness.

In Table 16 we present the effect of the intervention on applications, splitting the effect by initial geographical broadness. Column (1) and (2) show that this provides no new insights: the effect is not different for geographically narrow and broad participants. The same holds for the effect on the number of applications (columns (3)-(5)), which does not appear to depend on initial geographical broadness.

In Table 17 we present the effect of the intervention on interviews, again splitting the effect by initial geographical broadness. Rows (2) and (3) show that the positive effect on interviews is most pronounced among those that were initially geographically broad, though the coefficient is positive for

both groups. In rows (4)-(7) we find that with the exception of those that were occupationally broad and geographically narrow, all groups have positive effects, though due to larger standard errors not all are significant.

Table 15: Effect of intervention on listed vacancies - extensions

## **Online Appendix**

Results in this appendix are intended for online publication.

### **OA.1 Consent form**

# **Consent Form for Participants: “How Do Unemployed Search for Jobs?”**

**Thank you for your willingness to consider taking part in this study. Please read the information below carefully. By signing the consent form below, you indicate that you have understood the purpose of the study, you have been made aware of your rights and you have agreed with the terms and conditions of the study.**

## **Purpose of the study**

The study is undertaken to understand better how people search for jobs. The study aims to observe how people search for real jobs. The goal is to document parts of the job search process.

## **How will this work?**

The study will be conducted over a period of 12 weeks and you are asked to take part to one weekly session of 2 hours taking place at a pre-agreed time slot. You will be asked to come to our computer facilities, located at the School of Economics, 31 Buccleuch Place, EH8 9JT Edinburgh. There will be a maximum of 30 participants present at the same time in the facilities. The research team aims to provide an environment that is conducive to the job search of participants and hopes that participants will attend for the duration of the study or up to the point you find a job.

You will be able to spend most time each week to search for job vacancies. These job vacancies are obtained from two sources:

- Our main data source is the vacancy database of Universal Jobmatch and coincides with those used at Jobcentre Plus.
- Additionally, our database includes a small number of vacancies (no more than 2 per 100 vacancies) that is added for research purposes. These “research vacancies” are included to understand better which types of vacancies people are interested in even if these are not currently offered. If you express interest in such a vacancy, you will be immediately informed that this is a research vacancy before you start any application.

We will track the pages you consult, what vacancies you are looking at and consider applying to. This information will never be linked to any of your personal information such as your name and address, which will be stored separately. Your personal information will never be given out to anyone and will be accessible only to selected members of the research team.

You will also be asked some survey questions about your job search in the past week and your wellbeing. In the initial week, we will also ask a number of questions about your background and unemployment history. Six month after the end of your participation we will send you a survey about your labour market experience and your well-being.

Note that we ask all participants to stay for the full 2 hours in the laboratory. But if you do not want to search for jobs anymore, we provide some alternative ways in which you can use the computer and internet facilities.

If you are unable to participate to a session, please inform us as soon as possible (under [jobsearch@ed.ac.uk](mailto:jobsearch@ed.ac.uk) or 0131 6508324). The research team will attempt to provide additional slots in case a participant misses his time slots for justified reasons (e.g., job interviews, illness).

### **Important notes**

- Participation to this study is entirely voluntary. You should by no means feel compelled to participate. You can also withdraw from the study at any time if you wish to do so.
- Since the study is to gain understanding in how people search for jobs, the research team holds no particular view on how individuals should search for jobs. Thus, you should search for jobs in the same way as you would normally do.
- The study is conducted by the research team, and no personalized information is shared with any other organization. Therefore, no information will be shared with Job Centre Plus or the Department of Work and Pensions. If you would like to obtain a record of your search activities, e.g. to use for discussion with your case worker, you can obtain a printed record to take along at the end of each session.
- You should be aware that **participation in this study does not provide any additional benefits**, and in particular it does not provide particular help in job search. In particular, you **should follow your usual job search strategy**, such as for example looking at other job vacancies beyond those provided in our database, searching from home via the internet, and contacting friends and acquaintances. You should not take the time within the study as an indication of the appropriate time to spend on searching for a job.
- All the data collected during your time in our computer facility is anonymous. Your search activities will not be matched to your identity in any way. You will be attributed a randomly generated number at the first session and all data records will be matched to that number.
- We will ask you for a telephone number that we can use to contact you. We will only contact you to remind you of the time slot you have been allocated to and to inform you of any changes in schedule. Of course the telephone number will not be matched to the data we collect in the laboratory.
- You have the right to withdraw entirely from the study (i.e. ask us to delete all the data records associated with you) at any point during the study.
- The impersonal data collected will be used for research purposes (and ONLY for research purposes). Personal data will never be given out, and will be eliminated after the study is completed. The results of the study will be published in peer-reviewed scientific journals.

## **Compensation**

You will be compensated for your efforts of coming to and participating in each session in our computer facility with a compensation of £12.50 per visit (2 hours) to the laboratory. Additionally, if you participated in all four sessions in the first four weeks you are entitled to a £50 clothing voucher for job market attire as compensation for arranging the visit every week. The same holds for weeks 5 to 8 and for weeks 9 to 12.

## **Eligibility**

Participants have to be at least 18 years of age, permanent residents of the UK and living in Edinburgh (or within a distance of 5 miles from Edinburgh). You should be seeking for a job for a period of 4 weeks or less at the start date of the study.

## **Signature**

If any of the material above is unclear to you, or if you have any doubts and would like clarification, please consult a member of the research team before proceeding.

If you are willing to take part in this study, please sign the consent form below:

**I certify that I voluntarily participate in this research study. I certify that I read and understood the information above, and am eligible for taking part in this study.**

-----  
(please print your name)

-----  
(please sign)

-----  
(place and time of signature)

## OA.2 Lab instructions

## **UNIVERSITY JOB SEARCH STUDY: INSTRUCTIONS**

**Please do not start using the computer before we indicate you to do so.**

**We will read these instructions aloud at the start of the first session.**

### **INTRODUCTION**

Welcome and thank you for coming here today. Before we explain how each session will work, we would like to raise your attention to the following:

- **Health and Safety:** There will always be one person from the research team in the computer room. There is one toilet on this floor that you are free to use. In case of fire, please do follow the signs for fire exit. The main exit is through the staircase you have used to come up here.
- **No smoking:** Smoking is not allowed in this building.
- **Silence:** Since there are many of you in the room, we would appreciate if you would keep silent, so that everyone can concentrate on their computer activity.
- **Mobile phones:** Mobile phones must either be switched off or be on “silent” during each session. We would appreciate if you leave it on only if you are expecting an important phone call. And if you do receive a phone call, please leave the room and take the call outside (in the staircase).
- **Food and drinks** are not allowed in this room.
- **Questions:** Please do not hesitate to call us if you have a question.

### **WHAT IS THE STUDY ABOUT?**

The goal of the study is to understand how people search for jobs. Importantly, we hold no preconceptions regarding how people *should* search for jobs. We designed this study to find out what people usually do and what strategies are most successful. At the moment, we do not know what these are. We are interested in finding out common patterns in search strategies, and kindly ask you to search exactly in the same way as you normally would.

### **WHAT WILL HAPPEN IN EACH SESSION**

**When you come in, you will be assigned to a computer station. We may provide specific instructions at the beginning of the session, so please do wait for us to indicate the start of the session. We will now describe how each session will proceed.**

#### **1. LOGIN**

You have received a unique login number and password that you can use to login on the website here and also from home. You will be able to access your records using this login information.

## 2. SURVEY

Each weekly session will start with a **short survey**, asking questions about your past week and job search. After filling the survey, you will be re-directed towards the job search engine's main page.

For the first session, we will ask you to fill in a longer survey asking you questions about your background, qualifications and job search experience so far. You will only need to answer this initial survey once, in this session. It should take 20 minutes to fill in this initial survey.

## 3. THE JOB SEARCH ENGINE

We have designed our own job search engine. It allows you to search through all UK vacancies that are also recorded in Universal Jobmatch.

We ask you to search for jobs using this search engine only for a minimum of 30 minutes.

You can search using various criteria (keywords, occupations, location, salary, preferred hours). Importantly, you do not have to specify all of these. You just need to fill at least one of them.

If you specify more than one criterion, it is important to note that the computer will search for vacancies that satisfy all the criteria at the same time. For example, if you enter a keyword and you also select an occupation, it will search for vacancies that match both at the same time. Vacancies that match the keyword but not the occupation will not be shown.

Within some categories you can fill in more than one field. For example, within "occupations" you can specify up to two of them. If you do fill in two occupations, the computer that match either the first OR the second occupation. Vacancies that match one occupation but not the other will still be shown. You can also specify more than one pay range. This allows you to specify, for example, the hourly wages and the yearly wages that you are willing to accept. If you only specify hourly wages, it will not show vacancies that only specify yearly wages.

If you fill in your preferred hours, for example full time work, it will only list vacancies where the employer ticked a box that it is full-time work. Vacancies where the employer did not explicitly state that it is full-time work will not be shown.

If you leave a field empty, the computer will not use that criterion to restrict your search.

### Search for Jobs

You should spend at least 30 minutes searching for jobs in the lab, after which you will be able to view / print / apply for your saved vacancies and use the rest of the computer, you have been searching for 30 minutes.

Search for jobs by entering one or more search terms below.

General	Location and Salary
Keywords <input type="text" value="Keywords (e.g. nurse)"/>	Location <input type="text" value="Enter city or postcod"/> <input type="text" value="radius"/>
Occupations <input type="text" value="Select a category"/> <input type="button" value="v"/>	Salary <input type="text" value="min"/> to <input type="text" value="max"/> <input type="text" value="Select a"/> <input type="button" value="v"/>
<input type="text" value="Select a category then an"/> <input type="button" value="v"/>	<input type="text" value="min"/> to <input type="text" value="max"/> <input type="text" value="Select a"/> <input type="button" value="v"/>
<input type="text" value="Select a category"/> <input type="button" value="v"/>	choose up to 2 salary ranges
<input type="text" value="Select a category then an"/> <input type="button" value="v"/>	<input checked="" type="checkbox"/> Include jobs with no salary information
choose up to 2 occupations or categories	
Hours <input type="text" value="Select desired hours"/> <input type="button" value="v"/>	

Once you have defined your search criteria, you can press the search button at the bottom of the screen and a list of vacancies fitting your criteria will appear. You can click on each individual vacancy to get more information about it. You can then either

- **Save the job (if you are interested in applying)**
- **Do not save the job (if you are not interested)**

**If you save the job**, the computer will keep a record of the vacancy. You will be able to see all records of all saved vacancies at the end of the session.

**If you do not want to save the job and want to go back to the search results**, we will first ask you a few questions about why you are not interested in the job. Your answers are very important to us.

You can modify your search criteria at any point and launch a new search.

Note that we have also created a small number of vacancies ourselves (about 2% of the database), which are there for research purposes only. This is to learn whether you would find these vacancies attractive and would consider applying to them if they were available. We kept them to a minimum not to disturb your search. These vacancies will appear as all the other vacancies and may appear in your search results. But we will inform you at the end of the 30 minutes of any vacancy that may not be real. You will be able to see the list of your saved vacancies immediately after the 30 minutes are over, and we will indicate if any of them was an artificial one.

We may try alternative interfaces for the job search engine in the coming weeks. We will inform you if we do so and will explain the changes at that point in time.

#### **4. FREE USE OF THE FACILITIES (after 30 minutes)**

We will let you know when the first 30 minutes are over. You will then be free to use the computer for other purposes. You can of course keep searching using our job search engine, or you can do other things, such as write your CV, write a letter, or even send e-mails. You can use the facilities for up to 2 hours.

If you do not wish to continue searching or use the computer for other purposes, you are free to leave.

#### **END OF THE SESSION**

We can print a record of your job search for the day (just call us once you have finished), but only if that is your wish. You are free to show these records to your adviser at the Job Centre. They informed us that this would count as a proof of search activity.

Compensation: In general, you will receive a total of £11 as a compensation for your travel and meal expenses. This time, as you will soon discover in the initial survey, we do offer you the possibility of investing part of this compensation in this initial session. This is not compulsory. But if you do choose an investment option, your earnings will then be a function of what investment you have chosen.

Please collect your compensation from the registration room. You will get an envelope and be asked to sign a receipt. Note that the Job Centre has agreed that these £11 are a compensation for expenses and are not an income.

## **IMPORTANT NOTES**

### **LOG IN FROM HOME OR FROM ANOTHER COMPUTER**

You will be able to use our search engine from home or from another computer as well. You just need to log in on the website and use your login information. You will be able to see all the vacancies you saved and will be able to retrieve all the relevant information about them.

Note that as indicated in the consent form, all records saved are anonymous. These will not be matched to your names at any point.

### **YOUR COMMITMENT**

Note that it is very important for us that you come back every week and search in our facilities, unless of course you have found a job. If for one reason or the other you do have to cancel your session in a given week, please let us know as soon as possible. We will either try to reallocate you to another slot or ask you to search from home in that particular week. If you have found a job, please do let us know. This is of course of key importance for our study.

Also, importantly, you will receive a £50 clothing voucher for each four consecutive weeks you come. The first voucher will be distributed in the fourth week, that is, three weeks from now. The second voucher will be distributed in the eighth week and the third voucher in the twelfth week.

Thank you very much for your attention. If you have any questions, please raise your hand and we will come to you.

### OA.3 Lab instructions alternative interface

## **PLEASE READ**

### **NEW JOB SEARCH INTERFACE**

#### **IMPORTANT CHANGES**

We have designed a new search interface that should give you a better idea of jobs that might be relevant to you. This new interface suggests additional types of jobs (occupations) that are related to your preferred occupation.

You will be asked to specify your preferred occupation and the interface will return suggestions of other occupations that may be of interest to you. They may not all be relevant, but hopefully some will be relevant and will allow you to broaden your search horizon.

We use two methodologies to do this:

The first is using information from national labour market statistics, which follows workers over time and record in what occupation they are employed. The data records transitions between occupations and we can identify the most common occupations people switch to from a given occupation. We will ask you to indicate your preferred occupation using a keyword search and selecting the relevant title in a drop-down menu. The second is using information on transferable skills across occupations from an American website (called O\*net). For each occupation, we will suggest up to 10 related occupations that require similar skills.

Since the databases are different for each of the two routes, we will ask you to specify your preferred occupation twice and select it in the menu of possible occupations. So we will ask you again to indicate your preferred occupation using a keyword search and selecting the relevant title in a drop-down menu.

Once you have specified your preferred occupation for each of the two methodologies, you can then click “Save and Start Searching”

and you will be taken to a new screen that will suggest these new occupations to you.

The occupations will be listed in two columns:

The left column suggests occupation based on the first methodology (based on the UK labour market transitions). The right column suggests occupations based on the second methodology (O\*net related occupations).

You can select or unselect the occupations you find relevant and would like to include in your search.

We also have information about how competitive the labour market is for a given set of occupations. We have constructed “heat maps” that use recent labour market statistics for Scotland and show you where jobs may be easier to get (because there are many jobs relative to the number of interested job seekers). These maps are based on broad categories of jobs, not on each very specific occupation. You can click on the button “heat map” to see the relevant map. We would like you to try this new interface from now on.

It is nevertheless possible to switch back to the old interface that you have used in the previous weeks. You will see a button on the screen indicating "use old interface". If you click it, you will be taken to the old search engine interface. From there you can also return the new interface.

Thank you very much for your attention.

## OA.4 Baseline survey questionnaire

## INITIAL SURVEY

We will start by asking a few questions about your background and personality. Please fill in the answers as appropriate.

**Gender:** [drop down menu]

- Male
- Female

**Country of birth:** [drop down menu with all countries in alphabetical order]

**Ethnicity:** [drop down menu]

- Caucasian white
- East Asian
- Black African
- Black Caribbean
- Indian
- Pakistani
- Bangladeshi
- Other

**Age:** \_\_\_\_ [number]

**What are the first 3 letters of the postcode of your residence?** [EH1 until EH17 as dropdown menu]

My financial situation is deteriorating \_\_\_\_ [number]

Personal difficulties prevent me from focusing on job search \_\_\_\_ [number]

Health-related problems hinder my job search activities \_\_\_\_ [number]

### **Risk preferences question**

We now offer you the possibility to do a gamble with some of the compensation you will receive for today's session. You do not have to participate. If you participate, we will reduce your compensation by £2.80, but you will earn an amount of money depending on the gamble you choose and the outcome of the gamble.

We propose you 5 gambles. You can only choose one of them. Indicate your choice at the bottom of the page.

Each gamble corresponds to a flip of a coin and has two possible outcomes (Heads or Tail). We indicate below what you would win in each case. We will flip a coin at the end of the session, when you leave the room. Note that you do not have to play and you can simply choose to keep £2.80.

#### **Gamble 1**

**TAIL: £2.40                      HEADS: £3.60**

#### **Gamble 2**

**TAIL: £2.00                      HEADS: £4.40**

#### **Gamble 3**

**TAIL: £1.60                      HEADS: £5.20**

#### **Gamble 4**

**TAIL: £1.20                      HEADS: £6.00**

#### **Gamble 5**

**TAIL: £0.20                      HEADS: £7.00**

Your choice **[drop down menu]**

- I keep £2.80
- I play Gamble 1
- I play Gamble 2
- I play Gamble 3
- I play Gamble 4
- I play Gamble 5

### Time preferences questions

At the end of the session, one participant in the room will be selected at random and will receive lottery tickets (in addition to the compensation promised). Each ticket gives the chance to win up to £250,000. Note that the lottery tickets will be sent at the date indicated to the person's home address, so you will not need to collect them here.

Could you please indicate for each of the 15 choices below which option you would prefer. If you are selected, we will select one of the 15 choices at random and send you the relevant number of tickets at the date chosen.

Choice 1:       5 lottery tickets today       6 lottery tickets in a week

Choice 2:       5 lottery tickets today       7 lottery tickets in a week

Choice 3:       5 lottery tickets today       8 lottery tickets in a week

Choice 4:       5 lottery tickets today       9 lottery tickets in a week

Choice 5:       5 lottery tickets today       10 lottery tickets in a week

Choice 6:       5 lottery tickets today       6 lottery tickets in 4 weeks

Choice 7:       5 lottery tickets today       7 lottery tickets in 4 weeks

Choice 8:       5 lottery tickets today       8 lottery tickets in 4 weeks

Choice 9:       5 lottery tickets today       9 lottery tickets in 4 weeks

Choice 10:       5 lottery tickets today       10 lottery tickets in 4 weeks

Choice 11:       5 lottery tickets in 8 weeks       6 lottery tickets in 12 weeks

Choice 12:       5 lottery tickets in 8 weeks       7 lottery tickets in 12 weeks

Choice 13:       5 lottery tickets in 8 weeks       8 lottery tickets in 12 weeks

Choice 14:       5 lottery tickets in 8 weeks       9 lottery tickets in 12 weeks

Choice 15:       5 lottery tickets in 8 weeks       10 lottery tickets in 12 weeks
